Lectures

ON SOME

IMPORTANT POINTS IN CONNEXION WITH THE

SURGERY OF THE URINARY ORGANS.

Delivered at the Royal College of Surgeons,

BY SIR HENRY THOMPSON, F.R.C.S.,

SURGEON EXTRAORDINARY TO HIS MAJESTY THE KING OF THE BELGIANS, PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, EMERITUS PROFESSOR OF CLINICAL SURGERY, ETC.

LECTURE IV.

Impaired Vesical Function: its Various Forms and Consequences.

MR. PRESIDENT AND GENTLEMEN,—I have selected the subject embodied in the following title, "Impaired Vesical Function and its Results," because I venture to think that it is one which has not received the degree of attention from the profession which its importance demands. I feel little doubt you will concede that such an opinion is not likely to be expressed without sufficient warrant and due consideration. It is, however, a fact, which many years' intercourse with my brethren by way of consultation, not only here but abroad, has brought very prominently under my notice, that impaired vesical function is, among the many cases brought to me for solution, a morbid condition which is the cause of symptoms more frequently overlooked than any other in the range of urinary pathology.

[The lecturer cited various illustrations in support of this statement, and proceeded]:—

Let it be understood at the outset that the cases now alluded to do not necessarily belong to that large category in which hypertrophied prostate is the mechanical obstacle to the due performance of vesical function, and the indications of which are pretty generally, although not always, recognised. Prostatic change accounts for incompetency on the part of the bladder in a large proportion of cases, but it is by no means the cause in all. There are, indeed, numerous examples of impaired function due to causes in which disease of the prostate has no share. But before proceeding further we will inquire what are the natural functions of the bladder regarded as a reservoir of urine. The first function of the bladder is its ability to retain a considerable quantity of urine without occasioning any inconvenience to the individual, and without arousing in him any consciousness of its presence; and the mechanical attribute essential to the healthy organ is large extensibility of all its coats. The second function of the bladder is the ability to empty itself easily and completely at the will of the individual; and in order to accomplish this the coats of the reservoir must possess elasticity, which is a mechanical attribute, and also contractility, which is to be regarded as a "vital" one.

[The minute anatomy of the structures constituting the walls of the bladder was then briefly sketched, and their actions in relation to function described. The lecturer then continued]:—

It will now become sufficiently obvious how strong is the probability that various morbid conditions may have the effect of impairing the two vesical functions—viz., the one, of expanding, to retain a quantity of urine; the other, of contracting, to expel the whole of it—and that so delicate an apparatus may be deranged by more than one form of disease. And such is the fact. Regarding the views now generally received, I think that three chief modes by which impairment of the vesical retaining function takes place are recognised, and may be represented as designating three classes as follows:—

Class 1.—Enlargement of growth from the prostate, obstructing, more or less completely, the urethra at its entrance to the bladder, and so presenting an obstacle which the expulsive power of the bladder and associated muscles cannot surmount.

Class 2.—Loss of nerve-power to the muscles of the organ, constituting paralysis.

Class 3.—"Atony" of the structures of the bladder, invalidating their action, a term of doubtful import, and ordinarily so employed as to comprehend all other forms of vesical incompetence not designated by Classes 1 and 2.

The first class, constituted by prostatic hypertrophy and outgrowth, is familiar to all surgeons; and the frequency with which this condition impairs the vesical functions is sufficiently obvious. Nevertheless, its proneness to occasion habitual retention of urine is more frequently overlooked or disregarded than it ought to be.

It is not my intention to devote much time to this familiar topic, but in connexion with it there is a fact having an important bearing on practice to which I desire to call attention. An elderly man, who has been for some time annoyed with unduly frequent micturition, seeks advice and is treated by his medical attendant, who at first naturally endeavours to improve the general health, and does so, probably with some slight advantage to the local trouble complained of. Subsequently he suspects prostatic enlargement, examines his patient by rectum, and, finding no trace of it there, concludes that it is absent. Nevertheless, the most complete form of organic occlusion at the neck of the bladder may be present, giving rise to the symptoms complained of. There is little doubt that a very small prominence at the point named is not seldom the occasion of absolute incompetence on the part of the patient to relieve his bladder. While the effect of a very large hypertrophy is generally a modification more or less considerable of that function, the very small growth often arrests it altogether. The existence of the little eminence is not demonstrable during life by any means that I know of, although its presence may be suspected, and on good grounds be regarded, as probable. Now, the morbid condition before us is one which possesses an interest not merely for the collector of varied specimens for pathological classification, but also for the practical surgeon who aims at restoring a lost function, in this case one of extreme importance. It is notorious that during the present century, if not before, operations have been devised, chiefly by foreign surgeons, for dividing prostatic enlargements from the neck of the bladder by cutting instruments introduced by way of the urethra. These operations, it is quite certain, have not been attended with much success, although their partisans claim to have achieved excellent results by certain methods. Nevertheless, I do not hesitate to make this statement, because nothing would be easier than to produce persons who, having lost for years the function of micturition, and having depended solely upon the catheter, had regained their natural power as the result of operation; and no proof would be so strikingly conclusive, as the production of one such patient. Such evidence, however, has not been forthcoming; individuals have been met with who, suffering from retention due to some temporary although chronic cause, were submitted to operation, and the results have been claimed as examples of successful treatment by operation on an hypertrophied prostate.

I shall not discuss this topic at length, but having recently had the opportunity of investigating the latest proposal for thus operating, in the hands of my friend Professor Buttini, the accomplished professor of surgery at Pavia, I shall report the result of my observations in the following remarks. First, there is no ground for believing that any section or resection applied to cases of the enlarged prostate ordinarily met with can be resorted to with fair chances of success for restoring the lost function of micturition to the subject of it. On the other hand, any incisions or resections in a considerably hypertrophied prostate, which are adequate for the establishment of a permanently patent passage, must be regarded as extremely dangerous. Secondly, whether the obstruction be considerable, or whether it consist only of the little outgrowth which has just been described, when absolute retention has existed for several years, it is highly improbable that any operation will restore the natural power and enable the patient to dispense with the habitual use of the catheter. Thirdly, there is reason to believe that, in respect of the little outgrowth just named, should it be dealt with during the early stage of its existence, a division of the tissues may overcome the obstruction, and restore wholly or partially the function of the bladder. But Professor Buttini divides such an obstruction not with the knife, but by means of the electric cautery, considering the latter a safer and more efficient agent than the cutting instruments which he and others formerly employed for the purpose. Limited to the conditions named, I can conceive

Digitized by Google

that the operation may be a legitimate one, but circumstances so conditioned are not of frequent occurrence, and, when compared with those which characterise the cases ordinarily met with, are very exceptional. Professor Bottini's proposal differs widely from those methods which had been previously advocated as applicable to ordinary cases of hypertrophy, without the special discrimination or qualifications made above. Now, taking into consideration the degree of uncertainty which must exist as to the exact physical condition of the neck of the bladder in these cases, it appears to me that a more certain diagnosis, and therefore a more accurate division, if ever deemed necessary, might be achieved by the small perineal opening adopted for digital exploration and described in a preceding lecture. The patient, No. 41, in the series of cases there presented, offers an example closely resembling the condition described. I incised the neck of the bladder for him on account of its extreme rigidity, the only abnormal sign I could discover, and the relief it afforded was very marked, and it has been permanent.

In relation to the second class of cases—viz., those in which impaired or lost vesical function is manifestly due to an injured or diseased nerve-centre,—there is no occasion for discussion here: they are mentioned chiefly in order to define the residue which after them will remain for consideration. The examples of this condition, which occur from sudden injury to the spine, and from advanced and obvious disease of it, are sufficiently familiar to us all. It is necessary, however, to be watchful for slight defects in the supply of nerve-power impairing the vesical function, and usually associated with other slight local signs, indicating that chronic change is taking place in some part of the nervous system. Thus, a man, at or under middle age, states that for some time past the act of relieving his bladder has gradually required greater effort for its performance than formerly, so gradually that he does not know when he first noticed any change; that the stream has become habitually small; sometimes that the frequency has increased, sometimes the reverse, for he feels no want to pass it; generally he feels no pain, the urine is healthy in appearance, and by taste. The stream, moreover, does not cease definitely and unhesitatingly as in health, for after a little waiting and repeated effort, more urine can always be expelled, and the act may be considerably prolonged before the sense of having finished arrives, which, perhaps, after all, is not experienced. The local sensibility is diminished, for the consciousness of passing a stream is slight, a situation differing greatly from that which pertains to the small stream of stricture. Examination shows a healthy urethra, and can detect no enlargement or other physical deviation from the normal state of the bladder, prostate, and rectum. There is no history of over-distension, but the catheter finds two or three ounces habitually remaining in the bladder after a prolonged attempt to empty it. No other sign of a lesion in the nervous system is discoverable. Such a condition may turn out to be the beginning of a very grave history. It is possible that it may be the first indication of that affection of the cord known as tabes dorsalis, since that malady, in a few exceptional instances, is manifested by bladder symptoms at the outset, which appear at the close of the series in the usual order of its development long after the gait and the vision have been effected. As Dr. Buzzard has pointed out, the absence of the patellar tendon-reflex in such a case would go far to indicate that it was an example of tabes, a point relative to which I am seeking clinical facts.

Having thus eliminated from the list of causes of impaired function, hypertrophy of the prostate in all its forms, and all those of impaired nervous supply, we have now to consider what are the remaining conditions which occur to render the bladder incapable of contracting sufficiently to expel all or any of its fluid contents. Certain of these conditions are perhaps less commonly recognised than those just named, and come thus to be regarded as due to an affection termed atony of the bladder. This term has, in fact, become a convenient one, rather for the purpose of indicating that any given case does not belong to either of the two chief categories already mentioned than of affirming the pathological state of the organ to be that which the word "atony" implies.

The first condition to be noticed is chronic inflammation affecting the tissues beneath or outside the mucous membrane of the bladder. And it is worthy of remark that an inflammation affecting the mucous membrane only, impairs the function of the organ in a manner exactly contrary to that which is produced by the deeper inflammation referred to. That very common affection, ordinary cystitis, diminishes greatly, as long as it is present, the capacity of the bladder as a reservoir by impairing its first function, that of extensibility. Disturbance or movement of an inflamed mucous membrane excites pain, and the unfolding and opening out of the inner coat, necessarily produced by entrance of urine into the bladder, soon causes uneasiness, and this is instinctively avoided by repeated acts of micturition which relieve the patient. Such attacks, as a rule, pass off and leave the bladder almost, if not quite, as complete in its functions as before. But when repeated attacks have taken place or when prolonged inflammation has occasioned extension of the morbid action to the submucous tissue and the muscular coat, and if this has become also somewhat hypertrophied, a thickened condition of the walls of the bladder results in which the two functions of extending and of contracting on the fluid contents are imperfectly exercised. I have verified a few examples of this conjunction of inflammation and hypertrophy affecting the walls of the bladder to such an extent as almost to destroy their mobility, and at the same time to diminish greatly the capacity of the organ. The result has been inability to pass more than a few drachms of urine naturally, while the portion retained also amounts in quantity to very little more, and seems hardly to repay the patient for using the catheter, which, nevertheless, it is highly desirable that he should do three or four times daily. In such circumstances urine is passed every half-hour or so, and the interval, after using the catheter, scarcely reaches perhaps an hour.

Another cause of impaired function of the bladder is chronic inflammation of the prostate and neck of the bladder, usually following gonorrhœa. After aggravated and long-continued inflammation of the urethra, usually due to want of ordinary care, or to repeated exposure to fresh infection with irregular habits, especially to abuse of instruments, inflammation of the prostate occurs, and gives rise to a more or less persistent induration and swelling of the organ. The nature of this enlargement is, of course, wholly unrelated to that which constitutes hypertrophy; but its effect on the function of the bladder in regard of ability to empty itself may be to some extent the same. Although the quantity of urine habitually retained in consequence of this condition is not large, the troublesome symptoms will persist, and tend to increase, if the fact of vesical incompetence is not recognised and met by an adequate use of the catheter. One of the most common forms of muco-purulent urine with unduly frequent micturition, commonly called "catarrh of the bladder," met with before and about middle age, originates in this manner; and the essential cause of the "catarrh" is very frequently overlooked.

Again, failure to empty the bladder sometimes accompanies the presence of calculus there, and may persist for a time after the calculus has been successfully removed by operation. When calculus produces much pain in micturition—and pain as a symptom of calculus varies greatly in different cases—the patient sometimes learns instinctively, and quite unconsciously, to check the act of micturition before the bladder is empty, in order to prevent the severe smarting which occurs when, all the urine having been evacuated, the calculus remains in direct contact with the sensitive lining of the bladder. A habit of never quite emptying the organ is thus acquired, and persists subsequently to the removal of the stone by lithotrity, especially if the bladder remains tender and sensitive after the operation. But when lithotomy has been resorted to, and consequently the urine issues for several days by a perineal opening, the normal function gradually returns with the healing and closing of the wound, and the habit does not recur. The circumstance in question brings us to the consideration of a more important one—namely, the effect of lithotrity itself in impairing the vesical function, the two subjects being thus somewhat allied.

[This and several other causes of inability to empty the bladder by the natural efforts were dwelt upon at length. Then the subject of atony pure and simple was considered, and its nature and causes described, with numerous illustrations by preparations from the College museum. The lecturer then continued]:—

It follows from all the preceding considerations that our chief reliance for successful treatment in all the forms of impaired vesical function which give rise to retained urine is the habitual use of the catheter. And I must add that the remedy is not only most valuable, but that it is for the most part indispensable, and the sooner it is employed in the great majority of cases the greater is the chance of ultimate recovery, in addition to the immediate relief which the

Digitized by Google

instrument affords. It is the frequent failure to perceive this fact, especially in relation with the less obvious forms of incompetence, which has led, as I said at the outset, to my choice of the subject. The failure is due not only to the oversight of the pathological condition which demands mechanical aid, but to the strong and very natural disinclination which so widely exists to the employment of instruments. I had almost added to the prejudice which is entertained against them; and I fear that this also must be admitted. I cannot resist the temptation to cite in support of this statement an illustration which occurs while writing these very lines, and with an opportuneness which is remarkable, being in itself so completely appropriate to the subject. A gentleman from abroad, sixty-four years of age, called on me yesterday for the first time, to consult me after two years of continuous troubles from frequency of micturition, muco-purulent urine, the inevitable "catarrh," as it is termed, for which during that time he had been treated, notwithstanding which he had been steadily getting worse throughout. My first inquiry after hearing his story was, "Has a catheter ever been used?" The reply was, "No, indeed; may old friend and adviser," giving the name of a well-known foreign physician, "has always said, 'Whatever you do, never permit a catheter to be used; it is a machine which will create for you a worse malady than that which you already have.'" Such is the type of the answers I am accustomed to receive from foreign patients, and occasionally from my own countrymen.

The first sentiment which arises in my mind is astonishment that so grave a responsibility should be thus readily assumed by him who gives this counsel. Nevertheless, the frequency and the confidence with which it is tendered are very great; and I am bound to say that it has, within my personal knowledge, been the cause of many a premature and painful death. For when such advice is followed, the almost necessary, indeed the most common, result is that the patient, after much suffering and long endurance, becomes at last affected with complete retention of urine, for which a catheter *must* now be passed for the temporary mitigation of his tortures, and to prevent immediate or impending death. But the catheter is at this crisis not employed in any sense for the purpose of treating the original malady, as at first advised, and for which such relief has come too late, and ere long the patient sinks. The slender consolation at least remains, that the last few days of his life were rendered tranquil and comparatively painless by regular instrumental relief. Nevertheless, one almost invariably hears that the original adviser vaunts his foresight, and cites the catastrophe as a fresh warning against the catheter, which—as he asserts, almost, indeed, with an air of triumph—"was so soon followed by a fatal result." Well, terribly unjust as this is, and hard as it is to bear, it must be avowed that the dangerous and unwarrantable aversion to the instrument in many cases has not arisen without some sort of warrant from past experience in relation to catheterism; and this is the moral of my story, the facts of which are not exaggerated, and are such as I myself have, in varied form, but too often encountered. The surgical practice, at all events, which has preceded our time was not marked, in regard of the use of the catheter, by that gentleness and care, and by that choice of unirritating instruments, the value of which is now becoming recognised. The rigid metal catheters formerly adopted, together with the method of passing them, often studiously designed to exhibit the possession of rare dexterity, as indeed expressed by the very term 'tour de maître' used to denote it by the French — and mostly due to pretentious affectation — have in time past caused probably as much mischief as benefit to the subjects of it. These fashions have, to a great extent, passed away; but the popular traditions and the popular distrust of instruments will long remain. The rule for the student's guidance which I have long held to be imperative, and the importance of which I have reiterated, and now again repeat, may thus be stated:—The use of the catheter is in itself, to some extent, an evil; a very slight one if properly conducted, capable of becoming considerable in careless or unwise hands. A catheter is, therefore, only to be employed when the evil which is to be removed by its means may be regarded as more grave than that which is incurred by using the instrument; and such conditions as these are daily presented in practice. Let, then, every instrument employed be that which can be most easily passed, and is made of the least irritating material; always of course consistently with the efficient attainment of the object in view. Thus metallic or rigid instruments, as a rule, should only be used when those which are soft and flexible have failed; and for whatever purpose they should not be larger than the needs of each case demand. By such gentle treatment a very considerable improvement in most cases is certainly attainable; and in the course of time the greatly exaggerated antipathy which widely exists against the use of instrumental treatment in the bladder will gradually but certainly disappear.

I have one more caution to utter in regard of habitual catheterism for those elderly patients whose circumstances have been above referred to, which is of great importance. When the bladder has for a long period of time been overdistended—the patient's condition having been overlooked for months, or even for years, in consequence perhaps of catheterism having been forbidden—it is, at this advanced period of the case, a serious matter to resort to it. Rashly undertaken, great as is the relief at first experienced, symptoms of fever—"urinary fever," as it is, I think, properly termed — often appear in a few days; cystitis occurs, catheterism is required more frequently, the urine becomes highly purulent, the powers of life feeble, the tongue dry, nourishment is refused, and the patient sinks—usually in about three or four weeks from the first employment of the instrument. If an autopsy be made, almost invariably the ureters will be found dilated on one or both sides; one of the kidneys diminished in bulk and wasted, the other enlarged, inflamed, and perhaps the seat of numerous deposits of pus. It is said that such fatal histories following catheterism for long-continued distension of the bladder have occurred in individuals whose urinary organs, when examined after death, are found free from organic disease. Far be it from me to state that such a sequence of events is impossible; but it must be one of great rarity. No example has occurred within the range of my experience. When a patient whose vesical functions have been long impaired requires artificial relief, the best chance of saving him is to enjoin at once the recumbent position in a warm and equable temperature, usually in his bedroom, in order that the skin may act freely, and that no locomotion may be possible. The catheter should be used skilfully and with great gentleness; not at first emptying the bladder completely, but always removing the instrument when pain is felt, as it often is before that condition is reached; and it must be applied again as soon as relief is manifestly required. I can scarcely over-estimate the value of these precautions, nor advise too strongly the abstinence from movement and exposure of all kinds for a period of a few weeks in these particular cases. We may thus sometimes succeed in prolonging life, even at a very advanced term, and at the same time avoid the groundless but injurious opposition which is often manifested, as we have seen, to the use of the catheter; the want of which at an early period in the patient's history, and not the late recourse to it, has been the real cause of death in almost every one of the fatal cases described.

An Introductory Address

DELIVERED AT

THE CORK FEVER HOSPITAL,

At the opening of the Summer Session, May, 1884.

BY T. B. MORIARTY, A.B., M.D.,

SENIOR PHYSICIAN TO THE CORK FEVER HOSPITAL, AND PHYSICIAN TO HER MAJESTY'S PRISONS, CORK; RETIRED BRIGADE-SURGEON.

GENTLEMEN,—It will, I think, naturally occur to most of you whom I meet here for the first time that the duty of a specialist—for such we who are attached to a fever hospital must in a general way class ourselves—would be to tell you what you are to see in an institution of this kind, how you can in the quickest way learn what you will find useful in your calling, and how you will best profit by the instruction you will get here. From the outset let me impress you with the belief that if you study well, and carefully observe the outward symptoms of disease as you will see them here, you will be laying the groundwork of a good foundation, and be exercising a power of observation which is always the pass-

Digitized by Google

port of a good physician in whatever part of the world you settle in. In the more general class of ailments, especially those of the chest, you will also derive some useful information in your study of fever here. Indeed, I do not know if a hospital of this kind would not be the best place to learn all that we can of practical medicine with the varying degrees of disease, for, as you will see by all the fever hospital reports, fever is a mixed disease, and has in its train bronchitis, pneumonia, pleuritis, renal degenerations, abdominal congestions, acute inflammation of the brain and its membranes, disease of the throat, heart complications—in a word, nearly every form of disease to which the human being is subject may be developed during a febrile attack. For all this we would require a larger hospital; but as regards fever cases themselves, you could not, when well marked, see a more helpless class than the stricken-down patient, who is wholly incapable of helping himself, and at times unconscious of what he is doing. For this reason clinical medicine cannot be as easily or as comfortably taught as it can be in a general hospital. Still, you have a right to expect to be taught a good deal of what you may not see in other places; but the amount of risk you run in contracting illness is not to be lightly overlooked, especially when we are to study a class of diseases which is universally admitted to be contagious and infectious. On entering this hospital, you will perhaps feel somewhat timid; and it is not for me to inculcate habits of carelessness, or put forward any views which would be likely to lead you to suppose that in an institution such as this there is an exemption from the danger of catching zymotic disease. This is not so; and all I can say towards encouraging you in your studies is that none of those students who have preceded you have contracted disease. The professional men around us watch us closely, but as yet it has not been proved that a single case of disease has originated from the attendance of the hospital staff.

Having come thus far, I will take you to the bedside of the patient. You will find him in bed suffering, as you may expect, from pains in the head, a general sense of malaise, thirst, a quick pulse and high temperature—at all events, a temperature of 100°, otherwise he would not be here. For convenience sake only we may as well begin to study the condition of the digestive system. You will find the tongue covered with a white thick coating, which gradually increases in thickness towards the back, and at times it will be blackish. The tongue is red at the point, and also enlarged, as you will observe by the marks left by the teeth when it rests on them. Another symptom which appears early is loss of appetite, and this is most constant in cases of typhus fever, so much so that we look upon the demand for food as the first good symptom of returning health. When sordes or incrustations appear about the mouth and teeth we know that we are in the second week of the disease. I mention this as it will indicate the stage of the fever. These sordes are an accumulation of epithelial débris, which are rendered black by desiccation, or, as some writers say, by an admixture of blood. Bilious vomiting, or vomiting merely of the contents of the stomach, is not an unusual occurrence during the first week of fever, and this condition for the most part indicates disease of an aggravated type. You will examine the abdomen to ascertain whether it is rounded or flat, and pressure may indicate the presence of meteorism, which usually points to a want of nervous tone in the coats of the intestines. The existence of meteorism should at all times be regarded as a bad symptom. Abdominal pains and tenderness will be found to accompany all cases associated with diarrhœa. Constipation is usually present at the commencement of the illness, but as a rule the stools are of a normal consistence and colour, and their alkalinity, when it does exist, is in all probability due to the presence of ammonia. Bloody stools are rare. You must not, however, overlook their significance, for they are the sign of a bad and serious complication, and not infrequently the immediate cause of death. Barallier has described some cases which were accompanied with excessive hæmorrhage, and it will be always well to bear in mind that melanotic stools are a concomitant of scurvy. Whatever is the cause, we usually find that from the first there is an increase in the quantity of the urinary secretion, the urine will be at one time clear or loaded with lithates, or thick and red from an admixture of phosphates. The urea is also increased, and Frerichs is of opinion that the head symptoms and the delirium are not so much dependent on inflammation of the brain or its membranes as on the circulation through the brain of carbonate of ammonia which has been caused by the conversion of urea. The amount of chlorides is lessened from the first, and albumen has at times been found to be present at an early stage of the disease, and Oppolzer states he has found it present in almost every case of typhus, a statement I cannot from various examinations fully coincide with, although supported by Johnson and Gull. You will also observe that there is a peculiar sickening nauseous cold smell from the bodies of almost every patient affected with fever. This too is the product of an ammoniacal secretion.

When you come to inquire into the morbid condition of the nervous and muscular system, you will find headache always complained of. It is one of the first and most constant symptoms; it is felt for the first week, and often lasts for a few days only. It usually ceases with the advent of delirium, or about the eighth day of the illness. When it disappears from the head it may be complained of in other parts of the body. I mention this as a point worthy of your consideration, for the pains are of a fugitive character, and simulate, and may readily be mistaken for, rheumatism. The forehead and temples are usually the seat of pain, which in character is described as dull, heavy, and darting. Vertigo may also exist, which will be indicated by a giddiness which increases with the progress of the disease, and is aggravated by a horizontal position.

As you walk through the wards you will see some patients lying as listless as a log of wood, with every sense blunted from the effects of the fever; others, again, will be raving from delirium, which will point to, what you will invariably find, a disordered condition of the mental faculties. The degree of delirium and mental aberration will measure the extent of the disease. In most cases towards the end of the first week, the mental faculties become blunted and confused. The patient lies senseless, or he may be very restless, and the nurse will tell you he rambles in his sleep. On the other hand, the delirium may not appear until the second week, or shortly before you would be expecting some signs of convalescence. The character of the delirium varies. Most commonly it is of a low type, indicative of nervous disturbance. The patient lies quietly in bed giving expression to incoherent remarks, such as would not be used by a man in health, or he is restless and irritable, or gives an incorrect reply to your inquiry as to how he is; when asked to protrude his tongue he may ask for a drink, or something to eat. A second form is that known as delirium tremens—the result of drink. In this case the patient is restless, and usually suffers from insomnia, or the want of sleep, or he is labouring under a delusion. The pulse is found to be quick and feeble, the action of the heart is weak, and there exists a trembling or shaking of the limbs and tongue. There is also a third form of delirium, in which there is little or no sleep at all (as you have seen in the case of that poor patient, McC——), with a constant rolling of the head from side to side, and with frequent attempts, as you have heard the nurse describe, to leave the bed. The heart's action is excited, the skin hot and dry, the conjunctivæ are congested, there is an intolerance of light, and the delirium is at times of a most violent nature. In this period attempts to commit suicide are not unfrequent, as is shown to have occurred during the history of the Black Assizes: "Some, leaving their beds in consequence of their pains, would beat their keepers or nurses, and drive them from their presence; others, like madmen, would rush through the streets and lanes, and some again would leap headlong into deep water." This delirium of fevers is a most interesting study, and unlike anything you will observe in the delirium attending other disease. You will also as you go through the wards find some patients with a slight cough, and others with a dusky countenance, without any cough at all; nay, more, when you inquire about the patient's condition, or if he is troubled with cough, you may be told he has none. The cough accompanying bronchitis is such as you will usually find, but the cough of pneumonia is by no means as symptomatic of this disease as you usually see it in congestion of the lungs; but on auscultation you will find the peculiar crepitation, probably deep seated, without the coexistence of cough. This condition is not so well understood, and some writers think that this is owing to the deep seat of the disease, which has not as yet been in communication with the larger bronchial tubes; or, again, it may be attributed to the feebleness of the respiration, which at times is of a peculiar nervous kind, and so weak as not to produce increased respiratory action. But whatever is the reason,

Digitized by Google

you will find this condition frequently to exist, and for this reason I would advise you, whenever there is well-marked maculation, to examine for this condition. A patient has quite enough pain to contend with in fever without overlooking or disregarding serious complications, and these require to be treated as part of the disease. In consequence of increased temperature, thirst, and all the signs peculiar to febrile disease, one may easily overlook such complications; but bear in mind that you will only do your work well when you embrace every part of it as a duty. At no time should you treat lightly disease affecting the mucous surfaces, as it quickly produces embarrassed respiration, especially in diphtheria and malignant scarlatina.

The diseases we have alluded to, and their complications, which you will every day have an opportunity of seeing, must all be considered as belonging to the zymotic class. They are for the most part originated in and bred by filth and dirt, and as such with good measures of enforced sanitation should cease to contribute as largely as they do to increase our death-rate. The liability to disease exists in each of us, and only awaits until the proper time for its development has arrived. If this is so, and we doubt it not, you would be as likely to contract fever in your walks in life as you will here; nay more, if fever is an inbred poison, you will be as predisposed to contract fever in the wards of a well-ventilated hospital, as you will while sleeping in your own homes; and these remarks will apply with greater force to the home of the poor man.

The consideration of this question will lead us to a short inquiry of the germ theory of disease, which has now become a kind of household word amongst us. But it is only right that I should tell you that there are still some physicians who do not accept this theory, which has been created by the advance of sanitation. This theory assumes that many of the diseases which spread as epidemics are propagated by germs or spores, which produce disease when they meet with a suitable nidus, and soon after denote their existence by specific disturbances which characterise disease of this class. The advocates of this germ theory hold that those diseases which are known as zymotic are the result within the body of minute organisms which bear a resemblance to those which produce fermentation. These observations have been proved by facts and experiments which render them almost indisputable; and recent investigations have gone further, and shown that phthisis may be communicated by minute living organisms. In the case of two of the zymotic diseases—viz., cholera and enteric fever, and these are the most destructive of the entire class—it has been proved beyond doubt that water contaminated with sewage which has been infected by patients suffering from these diseases is capable of producing the same class of disease amongst those who drink the infected water. This is now so thoroughly recognised that the dread of epidemics is to some extent lessened by sanitary precautions; and a great deal more good would be done by introducing a pure water-supply. The one great question which will for the future engross the public mind is how infectious disease is spread. On this subject we can only remark that we must first of all look to our surroundings at home, next to what we eat and drink, and we must carefully distinguish between fancy and reality—in a word, we must go to the feeding ground of our supplies, and find out if the source is good and healthy, and then trace it to its destination. It may be well to go a little further and examine your homes, the method of cooking, and the water-supply, as well as the place in which the supply was kept before using. These remarks especially apply to one commodity—milk; for, if originally pure, it may be made infectious and the direct medium for the propagation of disease. This infection may be acquired by means of adulterations, or dirty vessels, or by being kept in a polluted atmosphere or in places where infection can be acquired. I could easily point out such sources, but my duty is to direct attention to them. When you have spent some time here you may find it really difficult to assign a reason why typhus should be the prevalent fever in this country, and more difficult still to say whether it depends on insanitary conditions or the habits and character of the people. We cannot, when everything is considered, attribute this disease to a density of population or crowded localities, for we rarely find this disease nowadays to prevail in gaols, and the dirty condition of some of those who go there is very loathsome. Whatever is the cause of fever, the best remedy to prevent its propagation will be found to exist in an early notification of its presence, and a close sanitary inspection of all dwellings and water-supply. Children in whose homes zymotic disease (by which we understand scarlet fever, small-pox, and measles) prevails should not be allowed to associate with young children in school, or the schoolroom will soon become the direct medium of infection. This is not as strictly observed as it should be, for parents, it is to be feared, are not sufficiently cautious about keeping the children at home as long as the disease exists, and such a system of carelessness will go on as long as schools are judged of by results and large attendances. By way of precaution, it would be desirable that as soon as the master notices a child with a rash on the skin, or hears that other members of the family are ill at home, he should insist on the child being examined by a medical man.

Water in an ordinary way can be purified by means of filtration, and this is within the reach of everybody. But to derive great benefit from this, the filters should be frequently cleansed and carefully washed, or they become a medium of disease, and greatly increase those organisms which produce and propagate disease. Spongy iron, or iron and charcoal, form the best kind of filter. In whatever way we may look on this theory, there is no doubt a great advantage to be derived by a knowledge of the way in which disease is produced, whence epidemics come, how they grow and spread, and how they may be prevented. It is at the same time our duty to explain to you the nature of the theory which forms the foundation of the modern treatment of infectious disease, and the means by which these disorders can be stamped out. It is no wonder that scientists should differ over this germ theory, and there are many who prefer to assume that these diseases are produced by chemical and other such allied conditions, rather than by the growth of living particles or germs. The question is therefore still to some extent an open one, but the great majority of physicians seem to accept the germ theory as the chief medium through which diseases of an infectious nature are propagated. Maclagan, in his work on the germ theory of disease, says, "This theory is that many diseases are due to the presence and propagation in the system of minute organisms—i.e., living beings having no part or share in its normal economy. This it is, and no more." It is essential to be clear on this point, for the opponents of this theory have introduced into the discussion the question of the source and origin of these organisms, when the question in reality should be whether or no germs *per se* can produce disease. Well, in what other way could we have this, or in what manner could we have disease without those germs, which lie dormant until the time for their development has come? This is not quite so new a theory; at all events, it is not the result of the labours of a few scientific men, for in 1668 Redi, physician to Ferdinand II. of Tuscany, found himself in opposition to the scientific men of his time, when he asserted that maggots in meat were produced by the eggs laid in the meat by flies, and not as the result of decomposition. This was also the belief of the ancients—viz., that living beings originated from dead matter without the existence or need of parents. Redi had to fight for his theory against the champions of spontaneous generation. To prove his facts he placed some meat in a jar which he covered with paper, and he showed that whilst the decomposition of the meat took place no maggots were produced. In another jar covered with gauze he was able to show that the flies attracted by the odour of decay came to lay their eggs in it. The gauze prevented their ingress, and the maggots were hatched on the gauze whilst the decomposition of the meat was going on beneath, and thus the question of maggots in meat was for ever settled, and the theory of spontaneous generation was finally abolished. After Redi's death the microscope was brought in to help scientific inquiry, and when animalcules were found in mud and water the question then arose how they could get there. It is now a well-known fact that heat and disinfection will destroy animalcules which are otherwise certain to appear. I will not dwell further on this topic on the present occasion, as we will have to refer to it again; but I think it right to express my adherence to this germ theory in a reserved manner only, for in our inquiries here we oftentimes find that febrile attacks are the result of cold and exposure. Even if we are to base our conclusions on our experience here, are we not always too ready, especially as regards the nature of infection and propagation of disease, to cry out when we find the members of one family or people in the same locality dropping off from illness one by one, that they have contracted typhus from one another? How is it with this theory when we go into a healthy locality

Digitized by Google

where we may find a solitary case only, as has lately occurred in the county gaol, where a man who had been imprisoned for over a year contracted, if you will, a well-marked maculated typhus, with chest complications? During this period some three thousand persons had passed through the gaol, and for four months prior to this man's admission there was no case of fever in the prison. At no time could I assign any other than an aerial cause for this and other isolated cases. Fever always shows itself by an increased temperature, which is the result of an increased consumption of tissue. The contagium is the causation of the fever, or, in other words, the germ, and, as a *post hoc* principle, we must believe that the germ is the cause of the febrile condition. The condition which characterises each of the eruptive fevers is not so much the result of a peculiarity in the febrile symptoms as the occurrence of local lesions. In this way, as Maclagan remarks, we find the true characteristic of small-pox in the eruption, of scarlatina in the eruption and sore-throat, of measles in the eruption and irritation of the mucous membrane of the eyes and respiratory tracts, of typhoid fever in the bowel lesions, of typhus in the rash and nervous prostration, and of cerebro-spinal meningitis—a disease which belongs to this class—in the extent of meningeal affection either of brain or spinal cord. Whatever may be the nature of this febrile condition we have to deal with as physicians, we can alone nominate it by means of the rash, which we find on the dependent parts of the body. It is certain we will have scarlatina without this rash and enteric fever without those pathognomonic spots which we look for in successive crops. I have treated many a case of typhoid without them, and when death took place, even in those cases of so-called simple continued fever, I found on post-mortem examination the peculiar and ragged ulcerations of the small intestines.

I fear an opening lecture of this kind would be considered incomplete if we did not give you some advice as to how you can best avoid catching fever. We have hitherto been so far fortunate that no student contracted contagious disease during the period of his attendance; and we can for this reason say to you, as we did to them, with greater confidence: Never try to beat up against time. Get up early and come here leisurely, after a good breakfast; and do not for any reason venture into the wards with an empty stomach, or in a heated condition, or at a time when your health is lowered by severe study or over-exertion. Remain in the wards as long as your duty only will require; and be careful when you are examining a patient not to inhale his breath; and also avoid dirty smells, observe extreme cleanliness, and wash your hands frequently. You have a right to expect from us, from the accidental position we occupy as your teachers, that we should bestow such an amount of time and attention as will enable you to thoroughly understand the nature and treatment of fevers; and if you carefully study the cases you see here for a few months you will obtain a thorough knowledge of one class of disease, and this the most appalling which can afflict the human being; for the ravings of the fever-stricken cannot fail to excite your sympathies. We will have much to say at the bedside; and when we ask questions of the patient, we do so, first of all, for the sake of judging of his capacity; and, secondly, in order that you may yourselves be able to see how our inquiry is conducted as regards certain signs and symptoms of the various stages as we find them. In after-life, when you are thrown on your own resources, you will find this method useful in helping you to unfold the histories of the cases you have to treat. For this reason you will, I trust, endeavour to follow us in such inquiry, as this will form the groundwork of more certain knowledge. We have no need to proceed in haste, and least of all to try and make you believe we know more of febrile disease than anyone else. Our position here is a twofold one—viz., that of teacher and student,—but with a responsibility from which you are exempt. Let us hope that our language and our demeanour will be always as respectful to the poor patients here as it would be if they were in a position to call us in to see them in their own homes; public and private liberality, for which this city is so well known, gives them a temporary home here. Never forget that kindness and gentleness not only mark the man, but also bring their own measure of consolation to those who are ill. Success in life can alone be gained by a high sense of duty, always combined with self-regard and industry. The upright physician knows no difference in his province between the rich and the poor man. Ours is a humane and charitable work, and I am confident none of those I see before me today will ever lower this nobility of our profession, which is the hereditary right of all of us. The honour, dignity, and independence of this position are yours as much as mine, and if your conduct and respectful bearing will only equal those who have preceded you in your walks through this hospital, we can then rest in the assurance that this dignity will not be lowered by you. Let us then endeavour to rob death of its pain and give consolation to all those who are placed under our care.

ABSCESS OF LUNG CURED BY INCISION AND DRAINAGE.

BY T. PRIDGIN TEALE, M.B., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE recent discussion at the Medical and Chirurgical Society on the incision and drainage of abscess of the lung renders the publication of the following case not only interesting, but also desirable, as a contribution to the discussion which has been raised on a very important question.

On March 1st, 1881, I was requested to visit Mr. B——, aged fifty-four, in consultation with Mr. Ireland of Tadcaster, and to tap a pleuritic effusion on the right side of the chest. The patient had been ill for three months, and had been seen occasionally by the late Dr. Shann of York, Dr. Clifford Allbutt of Leeds, and Dr. Myrtle of Harrogate. The earlier history of the case had been most obscure, commencing in December, 1880, with a cold, shivering, loss of flesh, vomiting and retching, and pain in the hepatic region, but there was no cough, nor any symptom of lung disease. Dr. Allbutt in the middle of February found the hepatic dulness increasing upwards, as if there were fluid in the lower part of the thorax, and a week later (Feb. 28th) Dr. Myrtle saw the patient, and, finding dulness occupying the lower half of the right lung, came to the conclusion that fluid was present, and advised early tapping.

On March 1st, 1881, after examining the chest, I came to the same conclusion as the other medical men—namely, that there was fluid in the pleural cavity. The right side of the thorax having been punctured low down with the small trocar of Bartleet's aspirator, a few drops of clear straw-coloured fluid escaped, and even after the addition of the suction of the aspirator only two drachms of fluid were obtained. Being still confident that fluid was present, I made a fresh puncture higher up, when very offensive, thin, greenish pus appeared, but only in drops. By applying the aspirator more pus was withdrawn, and after careful and continuous aspiration about a pint of pus was slowly obtained. My view at the time was that there were two separate collections of fluid in the pleural cavity, shut off by adhesion from one another. In consequence of the unexpected character of the case, two days later a consultation was held with Dr. Allbutt, Dr. Myrtle, and Mr. Ireland, and it was decided that as soon as the temporary relief given by the tapping had passed by, the thorax should be opened and drained.

On the 16th the patient had become more hectic, had expectorated for two days most offensive pus, and was altogether extremely ill. The following notes of Mr. B——'s condition were taken at the time by Mr. R. N. Hartley:—The chest as a whole was rather rigid, moving little during respiration, with perhaps slight inequality of movement of the two sides. The respiration was tranquil (30); the pulse 150. The left side was normal. On the right side there was continuous dulness below and over the hepatic area, extending upwards in front to about the level of the fifth rib, a little below the nipple, and laterally round the axilla, and diminishing towards the spine. In the recumbent posture there was a spot in the front of the chest having a peculiar "cracked-pot" resonance in the middle of a dull area. The area of the dulness was somewhat altered by change of position. Breathing but faintly audible over the dull area. No rales.

Operation.—An exploring trocar was introduced at a point a little below and in front of the angle of the scapula (ninth intercostal space), and a syringeful of fetid pus was withdrawn. The patient having been very cautiously put under ether by Mr. Hartley, I made, with the assistance of Mr. Ireland, an incision at the site of the puncture, and opened the pleural cavity. No pus appeared, only a small quantity

Digitized by Google

of serum. The finger introduced into the pleural sac discovered the lung, but no large space. The adjacent pleural surfaces were rough, and numerous adhesions were broken down easily by the finger passing in all directions. The lung felt dense and boggy, not crepitant and elastic. On reintroducing the trocar and puncturing the lung pus appeared. The puncture was enlarged so as to admit the finger, and two pints of most fetid pus escaped, rendering the room almost unbearable. A large drainage-tube about six inches long having been inserted, the cavity was syringed out with a weak solution of carbolic acid, and the chest was encased in carbolised tow, &c.

The after-progress of the case was extremely tedious and critical. As far as the local condition in the chest was concerned the treatment was comparatively simple. The cavity in the lung was washed out (at first three times a day) with a weak solution of carbolic acid or Condy's fluid, by means of a small catheter introduced along the drainage-tube. For three weeks the offensive character of the discharge continued, but at the end of this time it was comparatively sweet, though still considerable in quantity. On one occasion the patient expectorated a little pus, but this ceased spontaneously, and, with the exception of an occasional "suffocating feeling" when the cavity was being syringed out, symptoms directly referable to the lung mischief were not prominent. The patient's general condition, however, was for months one of the greatest anxiety, the symptoms being mainly those of septicæmic poisoning. Persistent vomiting, hectic, profuse sweating, delirium, and obstinate hiccough (lasting at one time almost incessantly for a whole week) were the most prominent features of the illness. At the beginning of July an attempt was made to move the patient to Scarborough, but was abandoned in consequence of a prolonged faint as soon as he was placed in the carriage. Later on, after a critical and dangerous attack of diarrhœa, the tongue cleaned, and he began to improve and to be able, almost for the first time for months, to assimilate an appreciable quantity of food at a time. The discharge from the sinus in the lung had all this time been gradually lessening, and the drainage-tube, which had been shortened at the rate of about an inch per month, was expelled spontaneously about August 24th, and could not be replaced, the sinus finally healing a few days afterwards. Before Christmas—i.e., within a year of the commencement of his illness, and within nine months of the incision into the lung—the patient had resumed his active work as a solicitor.

The following record of the patient's weight is interesting. On April 28th, 1881, he weighed 8st. 6lb.; on May 16th, 8st. 10lb.; on Aug. 1st, 9st. 2lb.; on Oct 27th, 10st. 10lb.; in November, 1882, 11st.; in June, 1884, 11st. 5lb.

Mr. Hartley visited Mr. B—— on June 6th, 1884, and reports as follows:—"He is not conscious of being in other than the most perfect health, is actively at work in his profession every day, and has no discomfort or shortness of breathing during ordinary exertion. The percussion resonance is equally good on both sides, all over the front of the chest, within the normal limits, and the breathing sounds are audible. From the right axillary line backwards towards the inferior angle of the scapula there is an area over which the resonance is much diminished as compared with the opposite side, and here the breathing sounds are faint and distant. This area may be considered as having its centre in the scar of the operation wound, and shading off into the more resonant parts. The circumferential measurements of the chest show a difference of half an inch in favour of the left side."

Remarks.—1. The surgical treatment of affections of the lung being as yet in a tentative stage, I have thought it well to report this case somewhat fully, as it is instructive in many points, is complete in its result, and, considering the age of the patient, is rare, if not unique. 2. Although in commencing the operation I thought the case to be one of empyema, my course would have been the same had I believed that the pus came from a cavity in the lung. It is clear also that the fact of the offensiveness of the pus ought to have suggested to me the probability that the collection was in the lung, and not in the pleural cavity. 3. The early history of the affection was most obscure. It seems not impossible that it commenced as a diaphragmatic pleurisy with a circumscribed empyema, which made its way upwards into the pulmonary tissue. 4. Another instructive point is this, that the first puncture with a small trocar only withdrew, even when aided by the aspirator, two drachms of serum; and that the pus was discovered by a second puncture. The pus also could not be withdrawn without the aid of the aspirator. 5. The case illustrates the importance of having an aspirator at hand when tapping a chest, to be used *only* in case the fluid will not flow spontaneously through the cannula and attached indiarubber tube. Bartleet's pocket aspirator is most convenient and useful, and does not apply suction too powerfully. 6. The question whether the opposed layers of pleura are adherent hardly affects the decision of the surgeon, chiefly because in the cases calling for interference it is impossible to ascertain the point, except by operation; secondly, because in suitable cases, in which as a rule there will be a large area of dulness, it seems probable that pneumothorax is not one of the factors that will arise to impair the prospects of success. Two cases of traumatic pneumothorax — not from broken rib — with healthy lung, under my care, have made good and rapid recovery. 7. This case is an additional encouragement to attempts to relieve surgically abscess and gangrene of lung. Such attempts will probably be most successful when the abscess can be reached and drained posteriorly through the ninth or tenth intercostal space.

Leeds.

ON

SUBSTITUTION AS A MEANS OF RESTORING NERVE FUNCTION CONSIDERED WITH REFERENCE TO CEREBRAL LOCALISATION.

BY VICTOR HORSLEY, B.S., M.B. LOND., F.R.C.S.,
ASSISTANT PROFESSOR OF PATHOLOGY IN UNIVERSITY COLLEGE, LONDON; AND SURGICAL REGISTRAR TO UNIVERSITY COLLEGE HOSPITAL.

SINCE in a complex piece of mechanical apparatus we find that loss of function is in proportion to the amount and seat of the injury inflicted on it, analogy will surely lead us to imagine that unless it is specially provided with a reserve of embryonic tissue in every part, the nervous system is no exception to this general rule. Although the purport of this paper is briefly to discuss the scientific value of the theory of substitution or compensation, it is impossible to go further without referring to the saving clause above mentioned—namely, the possible existence in the cerebral cortex at least, of numbers of small nerve corpuscles, connected with the veteran corpuscles of well-marked centres, but which have not yet themselves subserved psychical function. The existence of such corpuscles has been assumed by several writers at the present day, and with fair ground, seeing that in the first place the gradual accretion of knowledge by the child, and in the second place the intellectual acquirement of some new subject late in life, are both best explained theoretically on the assumption that fresh tracks are opened up with each new and complete idea. The bearing that this view has on the question of substitution is of course of fundamental importance, since supposing it to be true it is very easy to imagine that if a centre be destroyed, the elementary corpuscles in the uninjured area around having within themselves a faint echo of the nerve-disturbance which before was normally existent in their immediate neighbourhood can be educated gradually so as to replace the part injured. As yet this hypothesis has to be tested by experiments directly bearing on the point, such, for instance, as first extirpating a motor centre completely (vide *infra*), and then some weeks or months later exploring the portion of brain in the immediate neighbourhood with very weak induced currents. But even in the absence of direct experimentation, it is obvious that there are certain centres in the cortex destruction of which, or the fibres leading from them, is followed by permanent paralysis. Here, then, it is perfectly clear that even supposing the above theory to be true of a part of the cerebrum, it is not true of the whole, and therefore has no claim to be raised to the position of a working hypothesis based on broad generalisations. We will therefore leave this prefatory mode of accounting for the phenomena to which I have given the name of "substitution," implying thereby the same points as Dr. Broadbent[1] expressed under the term "compensation."

[1] Brit. Med. Jour., vol. i. pp. 333, 371, 401. 1876.

Digitized by Google

and, taking it (the development theory) as not proved, proceed to consider what are the most likely causes of the apparent restoration of function.

The theory of compensation or substitution imagines that when a portion of the highest mechanism of the nervous system is destroyed the opposite centres in the spinal cord take up the function, and are able to do so more or less completely in proportion to the extent of commissural union that may exist between such centres. Consequently, it is assumed that a development of nerve activity occurs whenever a patient really recovers from an attack of indubitable hemiplegia, and that the flow of nerve energy passes from the ganglion cells of the anterior cornua of the uninjured tract across by the anterior commissure to the cornual corpuscles of the opposite side, and so to the whilom paralysed muscles. This theory, as originally stated, assumed that the energy which caused a voluntary movement found origin in the corpus striatum, and ran down the pyramidal tract to the anterior cornual nerve corpuscles, thence passing out along the anterior roots to the muscles. This of course necessitated the view that the pyramidal tract terminated above in the corpus striatum, and below in the anterior cornua of the spinal cord.

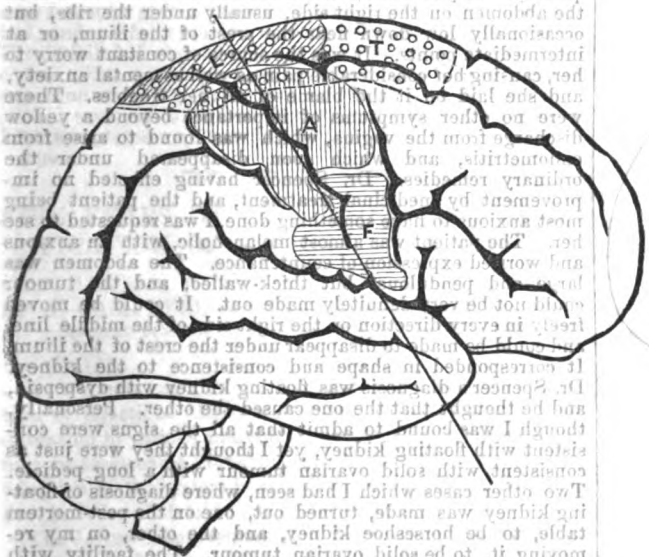
It is now perfectly clear, however, that so-called voluntary impulses arise from excitation of centres in the fronto-parietal region of the cortex, and descend along the direct pyramidal tract through the anterior two-thirds of the internal capsule, passing through the corpus striatum probably without the fibres forming any connexion with the ganglion cells of that body. Finally, there is reason for supposing that some fibres pass directly into the anterior root, either being connected indirectly with the cornual corpuscles, and so acting as a "side wire," while others are connected directly, as indicated in Fig. 1. Of course, the direct channels from the cortex are connected with the cornual cells, as is evidenced by the inhibitory effect which the higher centres exert on the corpusculate apices of the reflex loops, the removal of which influence from destruction of the said fibres by hæmorrhage, &c., followed by exaggeration of the reflex movements, is so striking a clinical observation. Although, from these amended considerations of the anatomical arrangement of the motor tracts in the spinal cord, it would seem that in a purely "voluntary" movement it is doubtful how much disturbance of the anterior cornual corpuscles occurs, still the mechanism for coördinated reflexes exists, and is connected with the descending tracts from the cerebrum, so that substitution is perfectly possible in the spinal cord.

FIG. 1.

T P D, Direct pyramidal tract. C A, Ganglion corpuscle in anterior cornu. *fa* and *fe*, Afferent and efferent tracks of a simple reflex loop. *fc*, Commissural fibre between opposite spinal centres. The efferent fibres are running into the anterior roots of the nerves.

But before passing on to discuss other methods by means of which the phenomena of gradual recovery of the paralysed trunk and leg in hemiplegia may be explained, it is interesting to note what movements are said to be bilaterally associated. Dr. Broadbent has pointed out that similar muscle groups are bilaterally associated in opposite limbs of opposite name—thus the left fore-limb with the right hind-limb. This relic of progression on four limbs probably is arranged in a special centre for walking, and so not necessarily in the spinal cord. Without going so far as to accept Nothnagel's *nodus cursorius*, in favour of which very little good experimental evidence has been offered, it would certainly seem very probable that the corpus striatum or some other highly coördinated ganglionic mass affords a corpuscular mechanism for progression, which in the lower animals is almost independent of impulses from the highest psychical centres in the cortex. Curiously enough, it is to be noted that a centre exists in the cortex of the monkey's brain close to the marginal convolution, following the stimulation of which there occur flexion movements of both limbs of the opposite side. But now the movements of the legs that are said to be "associated" are diametrically opposite to one another—i.e., flexion and extension; and we can see how rarely they do act in true concert from such an instance as when we try to flex both lower limbs at once, as in jumping from the standing posture. The amount of thought required to arrange the concerted effort is the best evidence of the rarity of the feat. Now, this has a very distinct bearing on substitution as it may be supposed to occur in the spinal cord, for that theory assumes that because the limbs are moved in concert in progression that therefore there is intimate commissural connexion between their respective spinal centres. But if there is any truth in cerebral localisation, then we should have a flexion and an extension movement combined, instead of both limbs moving in concert, or the formerly paralysed limb moving by itself in any given direction. To make this clearer, let us imagine that the case is one of right hemiplegia. Now, supposing recovery to be taking place, the theory of substitution would explain such by saying that the impulse which, proceeding from the right cortex, causes flexion of the left hip, travels across the cord to the opposite spinal centre, and produces flexion of the right (the formerly paralysed) hip. But since the flexion spinal centre of the left hip is associated with the extension spinal centre of the right hip, it is difficult to understand how the desired flexion occurs. In short, a fusion of function would occur; since with the same stimulus the muscles in both lower limbs would be responding to influences from spinal centres of opposite name. So that as far as the muscles surrounding the points of the segments of the opposite limbs are concerned, we can only look upon them as associated in a very definite way for a particular purpose. The muscles of the trunk walls, however, are different. Owing to the small amount of rotation permitted in the spine, these muscles do act in true association; consequently we rarely see one side act without the other, and, as far as flexion and extension go, always in the same way. This fact, however, falls more strictly under the heading of a double representation in the cortex, a subject on which a few remarks will be made in conclusion.

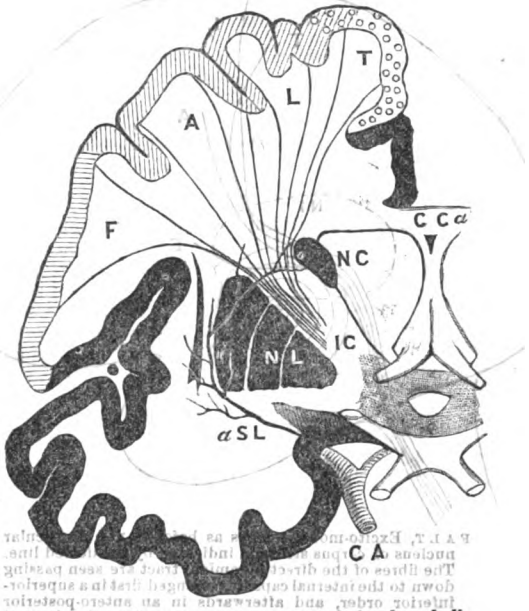
While still discussing the bilateral association of movements, the opportunity occurs of pointing out that there are two distinct points of view from which the action of a so-called cortical motor centre should be regarded. Thus a voluntary movement (and it may be safely assumed that cortical discharges from the fronto-parietal region form the motor side of volitional impulse) may either be (*a*) original and, in its details, novel, as far as the previous experience of the individual goes, or it may be (*b*) a complex movement greatly coördinated by hereditary influence and personal habit. The first of these is probably more frequently unilateral than the second, being usually limited to the peripheral segments of one or more of the limbs. But of course there is every degree of intermediate states between these two divisions of volition, just as the condition (*b*) passes by easy stages down to the lowest condition of a simple reflex action.



But to return to the original question—namely, as to whether the recovery of power in the trunk and lower limb in cases of hemiplegia can be accounted for other than by having recourse to hypothesis, I shall now seek to show that two further explanations of the same phenomena can be conceived to be at least possible if not probable. Since the cases which recover from an attack of internal cerebral hemiplegia show a steady improvement, after the first

Digitized by Google

effects of shock and "inflammatory" œdema (Bergmann) surrounding the injured part have passed off, it is somewhat surprising that some amount of recovery of function is not attributed to the gradual removal of pressure by absorption of the blood-clot, &c., since this process probably proceeds with considerable rapidity, remembering as we may the wide distribution of absorbent vessels in the cerebrum. Charcot[2] indeed does hint at this being probably the case in those instances where hæmorrhage in the neighbourhood of the internal capsule produces a transitory hemiplegia, the direct pyramidal fibres being intact. That this condition of things occurs in a simple case of intracerebral hemiplegia, where after absolute paralysis of the face, limbs, and trunk there gradually returns power in the muscles of the body and of the lower limb, is, I think, borne out by the following anatomical and physiological facts.

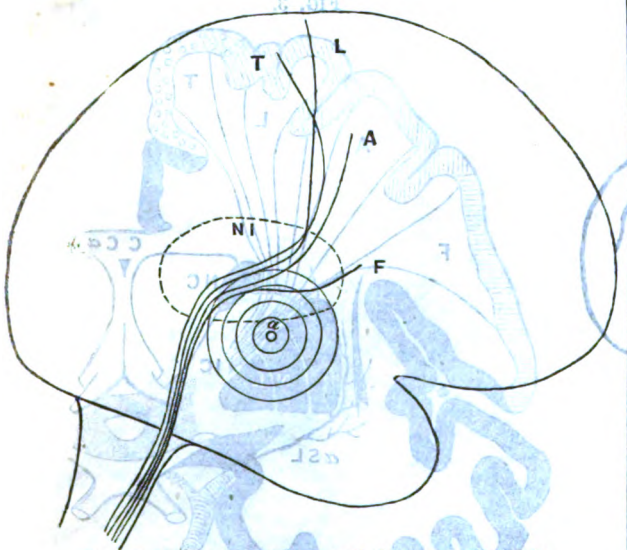


In the first place, a glance at Fig. 2 reminds us that, without going into detail, the cortical motor centres for the face and peripheral segments of the limbs lie grouped around the fissure of Rolando, as indicated in the diagram. The centre for the lower limb lies along the top of the sulcus, extending backwards into the parietal lobule and forwards into the superior frontal gyrus. The centre for the upper limb is next in order below, and occupies the middle third of the ascending frontal gyrus, and (according to Ferrier[3]) the middle three-fifths of the ascending parietal gyrus. Finally, the centres for the muscles supplied by the facial nerve are contained in the lowest third of the ascending frontal gyrus, and spreading across to the lowest fifth of the ascending parietal convolution. The researches of Prof. Schäfer and myself[4] have completed the list of cortical centres by finding that the muscles of the trunk are regulated by centres which lie in the marginal convolution on the mesial surface of the hemisphere. Moreover, we have shown that the centre for the lower limb dips largely over into the marginal convolution opposite the upper end of the fissure of Rolando. Now, if we carry a section across the brain (as described by Pitrès) nearly parallel to the fissure of Rolando, we see at once that the motor centres are arranged in the order from above downwards, of trunk and lower limb (intimately connected), upper limb, face, and that the fibres of the direct pyramidal tract which run down from these centres through the corpus striatum observe, of course, the same relative position. When opposite the centre of the lenticular nucleus the fibres become bent in entering the knee of the internal capsule, and, being twisted like the rays of a fan close to its hinge, now become arranged consequently in an antero-posterior manner, the most anterior being of course what was just now the most inferior. Consequently the fibres of the direct pyramidal tract viewed from the side are arranged as in Fig. 4, in which it is to be particularly noted that the fibres from the trunk and lower limb centres are first the highest and then the most posterior. Now, let us consider the source of hæmorrhage in a case of the kind we have imagined. This is now well known to be the lenticulo-striate artery described by Duret,[5] shown in Fig. 3, coursing round the under surface of the lenticular nucleus at the junction of the anterior and middle thirds, and then passing up through it and the internal capsule to gain the caudate nucleus. From this position it is obvious that hæmorrhage from it will destroy the pyramidal fibres in the order of, face, upper limb, lower limb, and trunk, as the focus of hæmorrhage will be below and in front of the bundles of fibres. Now, this is exactly the order observed clinically. In two cases in which I had the opportunity of watching the onset of the symptoms (one only twenty minutes after the first subjective sensation of giddiness, the other about ninety minutes after the patient first felt ill), the gradual invasion of the fibres supplying the groups of muscles was most striking, as each bundle was torn through by the advancing hæmorrhage. There ensued the customary fibrillar twitchings, and even tonic spasm, gradually passing off in a few hours into absolute paralysis, the order of the muscles involved being that stated above. Now, the converse of my proposition is equally true—viz., the recovery of the groups of muscles is in the reverse order, just as we should expect to occur, as clot and œdema fluid are slowly absorbed. If further suggestions are needed, it would seem to be in the direction of accumulating more definite records as to the degree of injury which the internal capsule suffers in such cases. It is obvious that the trunk fibres are as a rule only pressed upon, since if the hæmorrhage extended up as high as to completely divide them, it would be within a very few millimetres of the lateral ventricle, rupture into which would preclude further progress of the case.

FIG. 2.

Right hemisphere of the cerebrum, showing the centres in the excito-motor area of the cortex arranged round the fissure of Rolando in the order described in the text. F, Facial centre. A, Centre for upper limb. L, Centre for lower limb. T, Centre for trunk muscles. This centre being really on the mesial surface of the hemisphere, and so in the longitudinal fissure, is represented at its border by a dotted line. The straight line represents almost the plane of section shown in Fig. 3.

FIG. 3.



Section of hemisphere of cerebrum nearly in plane indicated in Fig. 2. It shows the relative position of the centres in the excito-motor area (lettering as in Fig. 2), the fibres running from the same into the internal capsule between the nuclei of the corpus striatum and the "artery of hæmorrhage." (DURET.) C Cα, Corpus callosum. N C, Caudate nucleus (corpus striatum). N L, Lenticular nucleus (corpus striatum). C A, Internal carotid artery. α S L, Lenticulo-striate artery. Hæmorrhage is usually most frequent in the outer zone of the lenticular nucleus, or just outside it.

Reference was made in a former paragraph to bilateral representation of groups of muscles in one cerebral hemispere, and this point will now be made use of to clear up some questions obviously left open in the above remarks—viz., the recovery of power in the face; and to describe the second conceivable means by which recovery of power in hemiplegics may be attained. It has been found by all experimenters in cerebral localisation that irritation of one facial centre on the outer surface of the hemisphere will produce identical (truly associated) movements of both sides of the face; so that we have here clearly both sides of the face represented in the cortex of each hemisphere. Under these circumstances we understand at once why a hemiplegic should recover considerable movement in the face while the arm remains absolutely useless, and while no doubt the pyramidal tract of the face centres is so much, or even more damaged than the arm fibres, according to the above description. But further than this, it is exceedingly difficult to analyse completely the movements of the trunk, and yet, judging from some experiments in which we obtained slight bilateral movements, it is highly probable that in man some of the trunk muscles (the pectorals and recti abdominis, for example) are represented bilaterally in both hemispheres. This being so, we thus have the second possible means of recovery of power, and therefore to be considered equally with the foregoing explanation. This is, of course, the position put forward by Dr. Hughlings Jackson,[6] except that he goes a step further, and believes "that all parts of both sides of the body are represented in each half of the brain," but "very unequally." On this point experiment lends no support to the assumption that the left arm, for example, is represented in the left hemisphere, and the rare recovery of the arm in complete hemiplegia is surely strong confirmation of the same idea.

FIG. 4.

PALT, Excito-motor centres as before. N I, Lenticular nucleus of corpus striatum indicated by the dotted line. The fibres of the direct pyramidal tract are seen passing down to the internal capsule, arranged first in a superior-inferior order, and afterwards in an antero-posterior order. The "artery of hæmorrhage" (*a*) is situated below and in front of the knee thus formed, so that the destructive effects of spreading hæmorrhage represented by the concentric lines will affect the fibres in the order before mentioned.

To sum up. Thus far I have desired to show that the phenomena of recovery of power in hemiplegia resulting from a lesion of the internal capsule may be either due to (1) removal of pressure &c. by absorption of the extravasated blood and its secondary products, or to (2) further development of function in the bilaterally acting cortical centres, and it seems probable that in most cases both agencies are at work. The question of the further development of a particular function in centres which already slightly subserve that function is one of fundamental importance, requiring to be fully investigated before we can explain instances of recovery of special sense where the perceptive centre has been destroyed. This, however, is too wide a question to enter upon at the present moment.

THE FIXATION OF MOVABLE KIDNEY BY SCRATCHING ITS CAPSULE THROUGH THE LOIN.

BY J. GREIG SMITH, M.A., F.R.S.E.,
SURGEON TO THE BRISTOL ROYAL INFIRMARY.

AT present, when the subject of displacements of the kidney is exciting considerable interest, notes of the following case, which was operated upon about a year ago, may be acceptable.

M. W——, aged thirty-nine, a largely-developed, well-nourished married woman, was admitted to the Bristol Royal Infirmary, under Dr. Spencer, in April, 1883, complaining of pain in the bowels, want of appetite, and constant headache. Six years previously she had suffered from a severe attack of inflammation of the lungs, and a month later she was confined of twins. Up to this time she had been strong and well, and her troubles came on subsequently. A year before admission she noticed a tumour in the abdomen on the right side, usually under the ribs, but occasionally low down near the crest of the ilium, or at intermediate points. It was the source of constant worry to her, causing her considerable pain as well as mental anxiety, and she laid on it the blame of all her troubles. There were no other symptoms of importance beyond a yellow discharge from the vagina, which was found to arise from endometritis, and which soon disappeared under the ordinary remedies. Dr. Spencer having effected no improvement by medicinal treatment, and the patient being most anxious to have something done, I was requested to see her. The patient was almost melancholic, with an anxious and worried expression of countenance. The abdomen was large and pendulous, but thick-walled, and the tumour could not be very definitely made out. It could be moved freely in every direction on the right side of the middle line, and could be made to disappear under the crest of the ilium. It corresponded in shape and consistence to the kidney. Dr. Spencer's diagnosis was floating kidney with dyspepsia, and he thought that the one caused the other. Personally, though I was bound to admit that all the signs were consistent with floating kidney, yet I thought they were just as consistent with solid ovarian tumour with a long pedicle. Two other cases which I had seen, where diagnosis of floating kidney was made, turned out, one on the post-mortem table, to be horseshoe kidney, and the other, on my removing it, to be solid ovarian tumour. The facility with which this tumour could be pushed down into the pelvis suggested the possibility that it also might turn out to be ovarian, and I recommended abdominal section, to remove it if not renal, to fix it if renal. This was accordingly done, and the tumour was found to be renal. There was no mesonephron proper, and the kidney was found very freely movable partly in the midst of, partly with a sort of flaccid bag of peritoneum and fat. When replaced it could be made to bulge in the loin, where it was readily felt through the skin and muscle. I hoped to be able to stitch it subcutaneously by carrying a long, curved, handled needle through the skin and the surface of the kidney, and tying the catgut suture over the muscles after making a punctiform incision in the skin. But the surface of the kidney tore and afforded no hold to the needle; so with one hand still in the abdominal cavity pushing out the kidney and ascertaining the course of the needle, and the other holding the needle outside, I moved the kidney surface in several directions over the point of the needle and left it *in situ*. I hoped that the organised inflammatory material so produced would be strong enough to retain the kidney in position.

The case pursued the ordinary course of a successful abdominal section. The antiseptic dressings were removed in a week; the wound was found completely healed, and the stitches were removed. On the fourth day there was a small amount of blood in the urine. All pain from the tumour was gone immediately after the operation, but about six weeks afterwards she suffered from diffuse irregular attacks of abdominal pain, not in any one spot, but generally all over. At this time she had abnormally frequent calls to

Digitized by Google

micturate, and these extended over some weeks. The tumour remained *in situ*, however, and there has been no sign of its reappearance since. I cannot say, however, that the operation has benefited the patient very much. She is nearly as low-spirited as ever, and though there is less abdominal pain than before, there is still a good deal, and the calls to micturate are still abnormally frequent. Possibly the near advent of the menopause may partially explain her symptoms.

Remarks.—I am no advocate of operative procedure in the case of either movable or floating kidney, and what was done in this case was rather as a sequel to an exploratory operation than as a deliberate attempt at fixation of the kidney. It would have been easy to stitch the kidney to the abdominal wall; but it is difficult to believe that an unprotected position close to the surface of the abdomen and in contact with its constantly moving walls can be much better than free movement inside the abdominal cavity. Again, I might have cut down on the kidney in the loin, and stitched its capsule to the tissues in the neighbourhood. This would have added to the danger of the operation, and would have rendered only the immediate result more certain, for sutures fixate only as long as they exist. When these are absorbed, the adhesions only remain to connect the united surfaces, and if the artificially inflamed capsule is kept in position while the adhesions consolidate the effect of sutures might be got. In this case, now that a year has passed, we may assume that the desired result has been attained. In another case I should give a thorough trial to treatment by rest in bed, and carefully applied padding inside an abdominal belt. If this failed, I should perform nephrorraphy by lumbar incision. But a case such as the above teaches us not be too sanguine as to the immediate good result of fixation, and should warn us to hold our hands for a long time unless the local symptoms were very urgent indeed.

Clifton.

FIVE YEARS OF THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES IN JARROW.

BY A. CAMPBELL MUNRO, M.B., M.R.C.P.E., D.Sc.,
MEDICAL OFFICER OF HEALTH FOR SOUTH SHIELDS AND JARROW.

AT a time when the question of the compulsory notification of infectious diseases is being hotly debated, and its extension to various individual towns vigorously opposed, it may be serviceable that some statement of the results of the adoption of the system in one of the towns in which it was first introduced should be laid before the profession.

The Jarrow Improvement Act, which came into operation at the end of 1878, includes the following sections, which detail the conditions of the notification system as adopted by the corporation of that borough:—

"35. In order to secure that due notice be given to the corporation of any inmate of any house who is suffering from infectious disease, the following provisions shall have effect (that is to say): (*a*) If any inmate be suffering from any such disease as aforesaid, the occupier or person having the management or control of such house shall, so soon as he becomes aware of the existence in any such inmate of any such disease, forthwith give notice thereof to the corporation. (*b*) If such inmate be not a member of the family of such occupier or person, then such inmate or the person having charge of such inmate shall, on becoming aware of the existence of such disease, forthwith give notice thereof to the corporation. (*c*) If such inmate so suffering as aforesaid is attended by a medical practitioner, such practitioner shall, on becoming aware that such inmate is suffering from any such disease as aforesaid, forthwith fill up, sign, and send to the corporation at the Town Hall a certificate or declaration stating, according to the forms prescribed and supplied to him by the corporation, the name of such inmate, the situation of such house, and the name of such occupier or person, and the nature of the disease from which inmate is suffering. (*d*) The corporation shall pay to every medical practitioner a fee of one shilling for every certificate or declaration given by him under this section. Only one such fee shall be payable in the case of one and same illness in the same house or family. (*e*) The corporation shall provide and supply gratuitously to every registered medical practitioner resident or practising in the borough forms for the certificate or declaration by such medical practitioner of the particulars herein mentioned in relation to such cases, according to the form set forth in the schedule to this Act. In this section 'house' includes any part of a house, and any building for the time being used for human habitation.

"36. Any person wilfully or without reasonable excuse offending against any provision of this part of this Act, or any order or regulation made under the provisions of this part of this Act, shall be liable on summary conviction to a penalty not exceeding five pounds, and in case of a continuing offence, to a further penalty not exceeding forty shillings for every day on which such offence continues."

Infectious disease is defined in Section 2 of the Act as meaning "small-pox, cholera, and fever." It will be seen that the duty of notification is laid both upon the householder and the medical man; practically, the notifications are received from the medical men. It happens that in the series of annual reports of successive medical officers of health for the borough, published up to the present time, the zymotic death-rates[1] of the five years preceding, and the five years succeeding the adoption of the notification system are given. Quinquennial periods are, I think, sufficient to furnish fair bases of comparison and to ensure the elimination of fallacies arising out of individual years of exceptional epidemic influences, such influences, for instance, as the prevalence of particular zymotics in adjacent districts. The following is a statement of the zymotic death-rates per 1000 of the population during the last ten years.

Pre-Notification Period.

1874.	1875.	1876.	1877.	1878.
5·7	5·1	2·9	5·1	6·9

Notification Period.

1879.	1880.	1881.	1882.	1883.
3·3	3·3	2·6	5·0	5·1

A simple calculation will show that the *mean* zymotic rate of the first or pre-notification period is 5·1, as compared with 3·8 in the period during which the notification system has been in force. The decrease—1·3 per 1000—in the *mean* zymotic rate of the second period, as compared with the first, is very gratifying. It will, however, be urged that there has been a considerable coincident decrease in zymotic rates all over the country. Such is indeed the case. I have tabulated below the zymotic rates in the fifty town districts with which Jarrow is included in the Registrar-General's returns, and with the zymotic rate of which that of Jarrow may most fairly be compared:—

Five years—1874-78.

1874.	1875.	1876.	1877.	1878.
4·4	3·5	3·3	3·1	3·3

Five years—1879-83.

1879.	1880.	1881.	1882.	1883.
2·9	3·7	2·2	2·9	2·4

The *mean* of the first quinquennial period is 3·6, of the second, 2·8; the decrease in the zymotic rate of the second period as compared with the first was 0·8. It will be seen that the decline in the zymotic rate in Jarrow is almost double that of the fifty town districts.[2] And the diminished prevalence of zymotic disease in Jarrow cannot be attributed in any degree to a proportional improvement in general sanitary conditions; the decline in the zymotic rate is not at all accompanied by a proportional decline in the general death-rate. The mean death-rate of the borough for the quinquennial period 1874-78 was 22·0 per 1000; for the period 1879-83 it was 20·5, the decrease being 1·5. Otherwise put, the proportion the decrease in the general death-rate bears to the mean death-rate of the first period is 0·068, while the decrease in the zymotic rate is in the proportion of 0·254 to the zymotic rate of the first period.

There may be towns in which in the same period a like gratifying decrease in zymotic rates has been experienced to that which has occurred in Jarrow; but I can hardly believe

[1] Death rates per 1000 of the population from the seven principal zymotic diseases.

[2] It is almost certain that the population in Jarrow has increased at a much more rapid rate in the last three years than is estimated by the Registrar-General's method; if this under-estimation of the population were discounted, the decrease in the mean zymotic rate of the second quinquennial would be fully double that of the fifty town districts.

Digitized by Google

that such decrease could have been brought about under circumstances so adverse as those in Jarrow, had it not been for the system of compulsory notification; for, in the first place, there has been in Jarrow a very rapid increase in the surface crowding of the population in the course of the last ten years. During that period the population has increased by about one-third; and, of course, density of population is an important factor in respect of the prevalence of zymotic disease. But the most adverse circumstance has been the want of hospital accommodation for the sufficient isolation of cases of infectious disease insufficiently isolated at home. Up till the year before last, Jarrow possessed no hospital, and even now the corporation only provides hospital accommodation for the reception of cases of small-pox. The sanitary officials are thus considerably handicapped in their efforts for the prevention of the spread of infectious diseases, for Jarrow is essentially a working-class town, and the lack of proper hospital accommodation is a much more grievous matter than in the case of the average town, as proper facilities for the sufficient isolation of cases of infectious disease at home are in a large proportion of cases wanting. With the compulsory notification and with hospital accommodation for, perhaps, three several infectious diseases (the provision of which the corporation has in contemplation), I have not the least doubt that a still more decided decline in the zymotic rate will be attainable in the next quinquenniad. There are defects, too, in the notification scheme adopted in Jarrow, which have detracted from the beneficial operation of the system. Thus, measles, from which disease alone there was a death-rate of 2·9 per 1000 in Jarrow last year, is not one of the diseases compulsorily notifiable under the Act. And the feeling of the medical men that they were very insufficiently remunerated for notifying had a tendency to make them not very enthusiastic in the work. An effort has been made to amend both these matters in a local Bill at present under the consideration of Parliament.

The notification system as wrought in Jarrow implies a considerable infringement of the "privacy of the home;" but I am bound to say that the visits of the sanitary officials are invariably received at least with equanimity—usually with courtesy, and that people generally seem willing to avail themselves of the advice I proffer. Each case notified is visited on the day on which the notification is received, by the sanitary inspector, and almost every case by myself as well; a formal notice to disinfect and a paper of simple instructions for isolation and disinfection are placed in the hands of the householder, information is given as to the times at which disinfectants may be obtained gratuitously at the Health Office, and the best practicable instructions for the isolation of the case—each in its particular circumstances—are given. I do not consider myself called upon to verify the diagnosis of the medical man in attendance; in any case, however, in which I have reason to question the diagnosis, and in which a different diagnosis would involve different arrangements for isolation and disinfection, I communicate in a friendly spirit with the medical man notifying. I have in no case made the corporation a court of appeal in matters of diagnosis.

A few words in conclusion, as to the general, apart from the statistical, results of the adoption of the compulsory notification system in Jarrow. Has the working of the Act aroused the hostility of the medical men of the town to the principle of compulsory notification? A sufficient answer in the negative was afforded in an experience of a few months ago. The corporation having resolved to incorporate some amendments to the notification system at present in force in a proposed new local Act, I was desired to convene a meeting of the medical men of the town, in order to ascertain their opinion of the various sanitary clauses of the proposed Bill. For this meeting, invitations were sent out to eleven medical men practising in the town. At the meeting which took place, after five years' experience of the system, no medical man was found to oppose the principle of compulsory notification of infectious diseases; two medical men, however, a principal and his assistant, held that medical men should merely be required to notify diseases as "infectious," leaving to the medical officer of health the duty of diagnosing the specific nature of the disease in cases notified. In this connexion, too, I may be allowed to remark that in spite of (?) the compulsory notification system, I am on amicable terms with all the medical men in the town; though I would not admit it as an argument against the system, that the medical officer of health in any town which had adopted the scheme was not on amicable terms with individual medical men, for there are some men in the medical profession, as well as outside of it, who would quarrel with their own shadows, and in respect of whom the meekness of Moses and the patience of Job would not avail to avert a quarrel.

With regard to the alleged tendency of the compulsory notification system to lead to the concealment of the existence of cases of infectious disease, I can only say that so far as my experience has gone I have seen no evidence of anything of the sort.

South Shields.

THE AFTER-TREATMENT OF

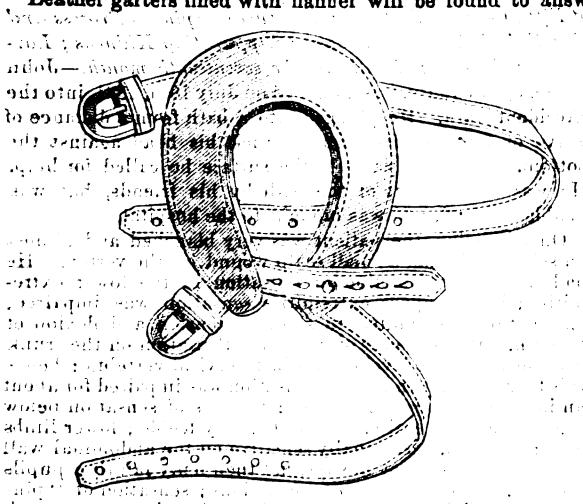
LATERAL DISLOCATION OF THE PATELLA BY A NEW FORM OF KNEE-CAP,

WITH THE OBJECT OF PREVENTING RECURRENCE.

By C. YELVERTON PEARSON, M.D., M.Ch.,
LECTURER ON DESCRIPTIVE AND SURGICAL ANATOMY, QUEEN'S COLLEGE, CORK, ETC.

THE difficulty of preventing recurrence of lateral dislocation of the patella, once it has taken place, is so universally acknowledged by surgeons that I am induced to publish an account of the success which has attended the use of a knee-cap devised by me (which I shall presently describe) for the treatment of the following case.

J. S——, a lady aged twenty-six, in January, 1874, when stooping suddenly, dislocated the right patella outwards, and immediately fell; soon afterwards she got her mother to extend the leg, when the dislocation became reduced. Next day the knee, leg, and foot became greatly swollen, and were treated with chamomile and poppy fomentations, followed by inunction of camphorated oil. She was obliged to keep the limb extended for three weeks, as the knee could not be flexed; and seven weeks elapsed before she was able to walk. She says that some swelling has since constantly remained in the knee below the patella. About nine months afterwards dislocation occurred a second time, and subsequently on three different occasions, the exact dates of which were forgotten. The case was first seen by me in October, 1881. The history at that time was that dislocation had occurred for the sixth time about six weeks previously, while running on the lawn after a child, when she experienced a sudden start, dislocated the patella, and fell. This time great swelling also followed, and the leg could not be put to the ground, but she got better in a few weeks, when an elastic knee-cap was used; soon after this was applied great swelling took place in the leg. When seen by me there was great œdema of the leg; the circumference of the knee-joint below the patella was an inch greater than its fellow; this increase was due to enlargement of the bursa beneath the ligamentum patellæ.



The following treatment was employed. I painted the knee with iodine liniment and applied a strapping over it, also a bandage from the toes. After a week the swelling of the leg was somewhat reduced, while that of the knee had almost disappeared. I then applied a Martin's elastic bandage to the leg, the use of which was continued till the œdema of the leg completely disappeared, which was not for some weeks. Knowing that the main point of treatment was to prevent a recurrence of the displacement, and not being acquainted with any suitable form of apparatus which could be worn constantly without inconvenience, I made a horseshoe knee-cap, which I shall now proceed to describe, and have illustrated by the accompanying sketch.

The appliance consists of a piece of dense poroplastic in the form of a horseshoe, the concave end of which is directed downwards, and embraces the patella pretty closely; this is covered on both sides by chamois leather, the posterior surface being markedly concave. The ends are connected below by a leather strap, with perforations for attaching it to a brass stud fixed in one end of the horseshoe. The presence of this strap permits a certain amount of separation and approximation of the ends to take place, with the movements of the joint, which could not occur if the knee-cap formed a complete ring, while at the same time offering sufficient resistance to prevent dislocation. By altering the connexion of the stud from one hole to another the cap can be made to fit different sized joints, though on the whole it would be more advisable to have the cap made specially for each individual. Attached to the outer border are two buckles, one near the upper, the other near the lower end; placed at corresponding

Digitized by Google

points on the inner border are two leather straps to go round the limb. These straps and buckles should be lined with flannel or silk; when applied one of these straps passes above the flexure of the joint, the other below.

The following directions will enable anyone with ordinary care to make this appliance. Take a piece of the most dense variety of poroplastic, about five inches square; while flat and in the hard state, cut it in the form of a letter U inverted, the concavity being made larger than the patella; then heat it in the usual manner till soft enough to be moulded; place it on the limb, held in a slightly flexed position; by now approximating the ends, and pressing back the convex border, the necessary shape can be readily imparted to it. It is of great importance to have the concave border cut so as to be at right angles with the surfaces, to leave its edges square, and to have the sewing near this border placed on the anterior surface, and not on the border itself; by attending to these points the cap will have greater power of resisting the edge of the patella when it tends to slip. The covering and fixing of the straps can be done by any shoemaker. Leather garters lined with flannel will be found to answer

very well. In the original form it was gutta-percha, and not poroplastic, I employed; but I have since chosen the latter, as being not liable to crack and more easy to mould.

Since the time I first devised the knee-cap the patient has constantly used one, and has had new ones made from time to time, about four having been made altogether; and at the time of writing this paper (two and a half years since the first one was made), the patient tells me that she never goes out without wearing the cap, and would be afraid to do so; that she has frequently experienced starts, and feels sure that dislocation would have occurred very frequently since but for it.

The following are the advantages I claim for the appliance:—1. That it is simple and easily made. 2. That it is inexpensive. 3. That it is light and offers no hindrance to the movements of the joint. 4. That it may be removed at night and reapplied upon getting up. 5. That it is not liable to produce œdema of the leg, which is so objectionable a feature in elastic knee-caps. 6. That it effectually prevents lateral dislocation of the patella.

Cork.

THE SECONDARY NATURE OF BINOCULAR RELIEF.

BY BRIGADE-SURGEON T. OUGHTON, A.M.D.

STEREOSCOPY is the visual modelling of solid forms by duplicate retinal impressions, seen to be coterminous with the natural field of vision, or a comparative miniature model such as is presented by the binocular coalescence of ordinary stereoscopic slides. Dissimilarity exists between ocular pictures as between those on a stereograph, but the resultant is no hazy spectrum consisting of duplicated images as taught by Brewster and adopted by many dogmatists; no, the relief-model is a perfect and complete whole, consisting of single objective points, infinitely superior to any sculptor's art, and far transcending the limited range appertaining to tactile ideas of solidity. Such being the general consensus regarding the experiential facts of binocular relievo at the present day, I do not purpose dealing here with the arguments of those investigators holding that any attempt to adjust the two different fields of vision must be a futile project.

Le Conte has very recently accepted the binocular relievo with single points, and he has arrived at very remarkable conclusions.[1] His hypothesis is that duplicate images of an object are actually presented to the sensorium, but that the points of the objects are seen single by a process of unconscious cerebration. He concludes, further, that visual relief is dependent on these double images, being a judgment that is based on duplicate impressions which do not emerge into clear consciousness; he has not attempted to analyse the judicial process beyond stating that it is an instinctive faculty, but he has dealt with the proof of double vision. He places a book in the median plane of sight with the back nearest the observer, so that the right side and upper edge shall be seen by the right eye, and the left side and upper edge by the left eye. When the eyes converge on the back the book is seen as if opening backwards, and when on the further edge as if opening forwards. We know that such must be the case, because the object is situated in the angle of binocular convergence or its extension; also we know that the above instance does not embrace all the facts of vision. Had the book been opened so as to correspond with the angle of binocular convergence, he would have seen the back only and nothing of its sides save monocularly and with visually single points. Had the book been opened still further, there would have been dissimilar retinal images of each side (four images in all); and it seems that the author would be compelled to admit that arguments proving double vision as touching the dissimilar images of a book in the median plane do not necessarily apply to the dissimilar images of each side of the book opened to an angle greater than that of binocular convergence. Each point of the sides of the book is seen single and in natural relief in the latter position. I desire to show herein that the relievo perception is an absolute one, entirely physiological, and owing nothing whatever to the modifying agency of a mental principle.

Another startling doctrine is that of Prof. Wheawell, who contends that the filaments of the special nerve (retina visibilia) must possess a power to contract and expand themselves so as to equalise the unequal lines and surfaces of dissimilar retinal images; his mental purview did not, strange to say, include the sole cause of every secondary perception—namely, the contraction and expansion of muscular filaments. Agassiz[2] has taught that a common sense imparts its aid equally to each eye, whereby inequalities are adjusted and dissimilar perceptions of perspective are rectified; his views are more nearly parallel to mine than those of any other expositor, for I propose that the common sense in question is muscular perception. Dr. W. B. Carpenter has, I think, justly credited to Professor C. Wheatstone the demonstration that we derive our perceptions of solid form or relief from the mental combination of the dissimilar perspectives that are projected by solid objects upon our two retinæ, with the following theses:—(1) That the mental combination is a positive process of receptivity, not appreciably different from analogous manifestations of the laws of motion, and (2) that the dissimilar perspectives in Le Conte's experiments with the book (an instance of double monocular vision) must be considered exceptional. It is certain, furthermore, that Wheatstone's demonstration does not define the causative ultimatum of relievo perceptions. This has been personally acknowledged by him, and he thought it probable that some law of vision might be discovered which should include all the circumstances under which single vision by means of non-corresponding points occurs and is natural. Bonnet[3] has observed that the union of the two retinal pictures into a single picture in relief still remains one of the most wonderful phenomena of the senses. He says: "The representation of the material world in a distinctly limited extent takes place in the brain, and as such will for a long time escape scientific research. Such is briefly accompanied the various solutions and views entertained by those accepting what appeared to be the truthful experiences of vision, together

[1] Dr. W. Mackenzie on Vision, p. 366, 1841.
[2] The Five Senses, p. 149, 1876.

with a few interpolations anticipatory of the present arguments.

In seeking a clue to the mental idea of relievo, the first essential is to ascertain the nature of relief in itself; it is subversive to progress to confound cause and effect, but nothing is more common than to make an independent mental principle the scapegoat for manifestations of the senses which elude ready comprehension by the intelligent principle. With no definition at hand, I shall offer the following for the want of a better. Relief is the compression of a magnitude within a second magnitude smaller than itself; it is the two sides of a triangle confined by the third side, or the arc of a circle in relation to its chord. Perhaps the best plan of studying relief is to divide a hexagon into its six natural triangles, and with these to build up successively a triangular, a quadrangular, and a pentangular pyramid; the six triangles in apposition, being limited by their equivalent extension only, constitute a superficies. Next, regarding the definition physiologically. (*a*) In regard o touch, the solidity of a tennis-ball held in the hand is a mental combination of the perception of its superficies in relation to the perception of its diameter. (*b*) Visually, Brewster has reproduced the diagram of a sphere by Leonardo da Vinci that is placed at such distance that exactly one-half is seen by each eye, the right eye perceiving a half inclining towards the right side, and the left eye a half inclining towards the left side.[5] In this case both eyes perceive considerably more than half the sphere, and yet the increased binocular magnitude is compressed within a visible diameter that is no greater than that perceived by each eye independently; hence the sphere is seen standing out in a bold relief.

Mental ideas of proximity and remoteness appertain to every visual perception of relievo, so as to differentiate between a foreground and a background; also the former ideas (proximity) are usually associated with the contractions of flexor muscles, and the latter (remoteness) with the contractions of extensor muscles. As a second essential to the present investigation, the ocular adductors will be regarded as a flexor arrangement, and the ocular abductors as an extenser arrangement, for: 1. It is now recognised that the apparent nearness of objects is dependent on the degree of convergence of the eyes; analogously, objects are brought and felt nearer during flexion of the muscles of the upper or lower extremity, and *vice versâ*. 2. Vision grasps an object as it were at the point of binocular convergence, in like manner as a flexor adjustment superintends the manipulation of a tangible object. 3. The eyeballs are rotated inwards during sleep, analogous to the semiflexed state of the limbs. This notion of ocular adduction being a true ocular flexion is, I believe, a novelty; but in a debate before the Academy of Medicine of Paris some years ago, M. Guérin, a distinguished orthopædist, maintained that strabismus was the club-foot of the eye. It must be noted next, according to a former demonstration, that the two external retinæ are under the sensorial surveillance of the internal recti (flexion or proximity), whilst the internal retinæ are influenced by the external recti (extension or remoteness). And, lastly, it must be conceded that the apparent position (distance and direction) of an object coinciding with the intersection of the two optical axes is absolutely fixed, as admitted by Brewster and others.

(To be concluded.)

THE SOCIAL SCIENCE CONGRESS.—Amongst the special questions which have been arranged for discussion at the next Social Science Congress, which is to be held at Birmingham in September, are the following:—Department of Jurisprudence and the Amendment of the Law: What reforms are desirable in the law relating to the arrest and continued detention of alleged lunatics, and to the control of their property? Department of Health: 1. What is the best method of dealing with (*a*) town sewage, (*b*) the products of house and street scavenging, and (*c*) the products of combustion? 2. What are the best means, legislative or other, of securing those improvements in the dwellings of the poor which are essential to the welfare of the community? 3. How far may the average death-rate of a population be considered an efficient test of its sanitary condition? and by what means can the high death-rate of children be reduced

GUY'S HOSPITAL.

TWO CASES OF FRACTURE AND DISLOCATION OF THE CERVICAL SPINE.

(Under the care of Mr. BRYANT.)

THE following interesting cases of fracture and dislocation of the cervical spine should be read in conjunction with the case reported below from the Halifax Infirmary.

CASE 1.—*Fractured Cervical Spine; Dislocation Backwards of Fifth Cervical Vertebra; Fracture of Spinous Process and Fourth Left Articular Process; Suppurating Kidneys; Lardaceous Disease; Death in the seventeenth month.*—John S——, aged twenty, was admitted on July 18th, 1881, into the Accident ward. He plunged into a bath from a distance of welve or fourteen feet, and struck his head against the bottom. When he came to the surface he called for help. He was assisted out of the bath by his friends, but was unable to stand, and was brought to the hospital.

On admission, the patient was very blanched and almost pulseless. He had a small scalp wound on the vertex. He had no power of motion or sensation in the lower extremities; in the upper extremities sensation was impaired, and motion was limited to slight extension and flexion of forearm, with no power of grasping. Sensation on the trunk was perfect to the level of the last cervical vertebra; below this there was a band where sensation was impaired for about an inch (in direction of nerves); the loss of sensation below this was almost entire. Pulse 62, very feeble; lower limbs cold; priapism, occasionally sensitive on the abdominal wall and genitals, but not always, and then only faintly; pupils normal; no vomiting; quite conscious; sensation of "pins and needles" down the arms; pain under the ear, cervical, and first dorsal vertebræ; temperature in mouth and axilla 97·4°; no facial paralysis or loss of sensation; no deafness; no hæmorrhage from ears or other symptoms of fractured base. The patient was unable to cough, and the attempt brought on retching and gasping.

July 19th: Unable to pass urine. Soft elastic catheter used.—25th: Priapism gone.—27th: Urine thick and ammoniacal.

Aug. 1st: Able to tell which toe is touched on left foot.—16th: There is returning sensation on left side of the abdomen, but none on the right.—20th: Breathing wholly diaphragmatic.

Oct. 12th: Urine 1020, reaction alkaline, no albumen.—17th: Legs are much wasted.—28th: Swelling and œdema of ankle and knee-joints.

Nov. 2nd: Sensation over right half of abdomen slightly improved.—19th: The patient has bedsores on his back, which has a spotted appearance all over, with a disposition to form sores.

Dec. 12th: Bladder washed out every two or three days with boracic acid lotion.

Jan. 2nd, 1882: The bedsores are healing, but fresh ones are threatening. He has severe sweatings.

Feb. 6th: The patient is able to read. Morphia is subcutaneously injected and a belladonna pill is given twice a day. His arms are flexed and supinated. He has sensation now to middle of left leg.

March 6th: Bedsores dressed with glycerine and boracic acid.

April 13th: For the last two days excessive perspiration has returned. Ordered five grains of sulphate of quinine, four minims of dilute sulphuric acid, and half a drachm of orange syrup, in an ounce of water, three times a day.

May 26th: For the last two nights the patient has wandered a good deal, and fancies that some one is poisoning him.

June 1st: Passed some blood and stained mucus this morning.

Digitized by Google

July 24th: The patient perspires less, and seems to be gaining flesh.

Aug. 24th: Complains of pain in the hypogastric region.

Sept. 11th: Complains of headache and jumping pain in the leg.—13th: Urine alkaline, sp. gr. 1020, no sugar, no albumen, and contains ropy mucus.—14th: Ordered seven minims of solution of strychnia, seven minims of dilute nitro-hydrochloric acid, fifteen minims of syrup of orange, with an ounce of infusion of orange, three times a day.—17th: The patient lies on his back with his arms rigidly contracted, the elbows close to the side, and the foramens tightly flexed on the arms and supinated, so that the dorsal aspect of each hand is in close contact with the front of each shoulder, the palms looking forward, and the thumbs tightly drawn inwards towards the palms, and the fingers rigidly contracted.

Nov. 22nd: Complains of excessive sweating. Tongue dry and rough.

Dec. 4th: Urine alkaline, sp. gr. 1015, with a distinct albuminous cloud. His temperature is curious — viz., Dec. 2nd: morning 97·5°, evening 102°; Dec. 3rd: morning 101·5°, evening 102°; Dec. 4th: morning 97°.—7th: The patient is constantly sick.—27th: Died.

Necropsy.—The bodies of the fourth and fifth cervical vertebræ were found to be firmly anchylosed together by a new bony layer in front. The fifth vertebra was dislocated backwards, so that the posterior lower edge compressed the cord greatly at this point, where it was much atrophied. The remainder of the cord below was small, firm, and apparently a good deal atrophied. There was no myelitis. The membranes were not thickened. The bladder was in very fair condition. Cretaceous nodules existed in the left apex of the lung, and patches like tubercle here and there. Heart good, pericardium adherent. Spleen large, firm, and translucent (lardaceous). Stomach darkly stained and decomposed. Liver lardaceous. Kidneys true surgical.

CASE 2.—*Fracture and Dislocation forwards of Fifth Cervical Vertebra; Complete Paralysis; Cystitis; Bedsores; Early Broncho-pneumonia; Death on the Forty-seventh Day.* (Notes by Mr. Penfold.)—Ellen D——, aged fifty-five, was admitted into the Lydia ward on Oct. 9th, 1882. She was found at the bottom of a flight of stairs at 10 P.M. on the 8th, sensible, but unable to move. She had fallen down, but how long before she did not know. She complained of a pain in her neck, and was put to bed. Her hands were cold, and she had no use in them. She slept through the night. The next morning (9th) she stood up, but immediately fell down. She was brought to the hospital in a cart at 2 P.M.

On admission, there was found to be complete anæsthesia up to the second rib; between the region of anæsthesia and normal skin was a distinct zone of hyperæsthesia; the paralysis extended below the arms; there was diaphragmatic respiration; and the elbows were flexed across the chest. The patient could tell when the great toe was touched.

Oct. 11th: The patient makes an effort to cough but cannot; the diaphragm acts, also the muscles of the neck, but the chest and abdominal muscles are immovable; she wants to be sick and cannot; the tongue clean at sides and tip, reddish-brown, raised down the centre, and edged with slimy white fur. She has slight voluntary movement at the shoulder-joint, but cannot raise her arm more than two inches. There is marked movement in the supra-clavicular region in respiration; the region of the hyperæsthesia not definable now; urine drawn off by catheter. A soap enema was given. Breathing laboured.—13th: Urine acid, rather muddy, no albumen, sp. gr. 1023.—14th: Urine ammoniacal.—17th: Slight involuntary evacuation of fæces; cough troublesome.—18th: Urine strongly alkaline, loaded with plastic mucous, sp. gr. 1020; bladder washed out with iodine and water.—19th: Bedsore on back extending. Urine under a quarter-inch lens showed triple phosphate and some organic substances, probably bacteria and epithelium.—25th: Bedsores extending; dressed with iodoform; bladder washed with borax lotion, washings blood-stained.—27th: Passes water involuntary; is conscious of being wet.—28th: Urine ammoniacal and fetid, contains albumen, blood, pus, mucus, bacteria, and epithelial scales.

Nov. 6th: The patient passes fæces and water involuntarily; has very troublesome cough; heart-sounds feeble and normal; loud rhonchi heard all over chest; no crepitation; legs somewhat œdematous.—17th: No albumen, and no sugar in urine.—23rd: Has caught severe cold, voice almost lost.—25th: Quite unconscious. Pulse 98; respiration 43, sudden and very short.

Necropsy.—There were dislocation and fracture of the cervical spine between the fifth and sixth cervical vertebræ, with softening of the cord; also early broncho-pneumonia.

HALIFAX INFIRMARY.

FRACTURE OF THE SPINE; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. J. K. WRIGHT.)

THE following notes, for which we are indebted to Mr. G. W. Crowther, senior house-surgeon, should be read in conjunction with the cases above recorded from Guy's Hospital.

J. L——, aged twenty-one, a slater, was admitted on March 25th. He stated that whilst at work on a roof he was carrying a stone slate on the top of his head, when he suddenly slipped and fell backwards, the slate falling on the back of his neck. He was not unconscious, but could not move his legs.

On admission he was considerably collapsed, the skin was cold and clammy, and the pulse at the wrist almost imperceptible; the pupils were contracted, but equal, and the expression was dull and sleepy. There was paralysis of both legs as regards motion, but tactile sensibility was perfect. The arms were unaffected. The intercostal muscles were paralysed, so that the chest wall sank in on inspiration; the breathing was entirely abdominal. There was priapism. A slight abrasion was noticed over the left frontal prominence. On the following day the temperature was 101° F. The hot bottles which had been applied to the feet and sides were taken away and the patient was ordered to be kept at perfect rest. Numbness and tingling of the lower extremities, extending upwards to the armpits, were complained of. There was also loss of tactile sensation in the right lower limb, extending upwards along the whole right half of the body as far as the second costal interspace. The patient could not distinguish between hot and cold bodies applied to either leg. There was no ankle clonus nor any plantar, patellar, cremasteric, or epigastric reflex on either side. The pupils were contracted, and reacted but slightly to light and distance. The patient complained of severe pain at the back of the neck. On examining the spine externally no inequality or irregularity in the spinous processes could be detected, but pressure caused pain about the lower cervical vertebræ. No bruising could be seen. There was constant vomiting of slightly acid, yellowish-brown fluid without effort, as well as persistent hiccough. The tongue was pale, covered with a slight brown fur; abdomen tense and tympanitic all over. The patient had passed no urine since admission, except by catheter, and there was absence of reflex of defæcation. Evening temperature 97°F., pulse 68, soft and compressible, respiration 24. Great thirst; ice given to be sucked. On the 27th the patient said he felt a little better, did not complain of pain, but had passed a sleepless night. Vomiting and thirst continued. Temperature 97·6°, pulse 76, respiration 28, urine drawn off by catheter. Very slight motion in both arms, but sensation perfect in them. At 8.30 P.M. he was found to be unconscious, breathing with great difficulty and entirely by the abdomen. The face was livid and the veins at the root of the neck were prominent. The pupils were dilated and the conjunctivæ were insensitive to the touch. On examining the chest rhonchial sounds were heard and the heart sounds were distinctly audible. Temperature 100° F., pulse 108. The patient died at 8.40 P.M.

Necropsy, forty-eight hours after death.—Body well nourished; post-mortem lividity marked; rigor mortis marked in lower extremities, slight in upper; pupils dilated and equal. There was a fracture involving both laminæ of the fourth cervical vertebra, the outer portion of the lamina overriding on the left and passing down on the left side into the lamina of the fifth. There was also fracture of the bodies of the above two vertebræ about their centres. There was a small blood-clot immediately under the seat of fracture, outside the dura mater. The spinal cord was flattened and indented posteriorly at the cervical enlargement. Rupture through the right antero-lateral column, extending slightly into the left half at the lowest part of the cervical enlargement.

Remarks by Mr. WRIGHT.—When this patient was admitted it was at once seen to be a very serious case, and from the account of the accident it seemed probable to be one of concussion of the spine. With the permanency of

Digitized by Google

the symptoms, however, it proved to be more than simple concussion. The group of symptoms pointed to injury and interference of power about the fourth cervical vertebra, this not being so complete as to thoroughly paralyse the brachial plexus, as evidenced by the involuntary drawing up of the arms, &c. As usual in such cases, this patient gradually sank from impediment in the lungs, dying from asphyxia. In a medico-legal point of view it is an interesting case, showing by how simple an accident we may have not only fracture, but also impaction of the plates of the vertebræ. As there was no evidence of direct violence to the neck, it is just possible that the man may have fallen on his buttocks with his spine quite erect whilst walking on the roof, and the stone slate which he was carrying might have remained on his head and its weight have thrown the head violently back, and so fractured the neck at the weakest point of the arch thus formed; this is supported by the small contusion found on the forehead. If this supposition is correct, I think it is an unusual mode of accident. I do not remember another instance of such injuiry being so produced.

MEDICAL COLLEGE HOSPITAL, CALCUTTA.

CASES OF ANEURYSM.

(Under the care of Mr. O'CONNELL RAYE.)

For the following report we are indebted to Anoda Prosad Datt, house-surgeon.

CASE 1. *Traumatic Aneurysm of the Palmar Arch.*—R. G——, Hindoo male, aged twenty-nine, received a wound two years previously in the left hand. The wound healed, but a pulsating tumour soon after formed near the hypothenar eminence. On admission the swelling was as large as a half walnut, and pulsated strongly. Pressure on the ulnar artery did not reduce the pulsation, neither did pressure on the radial; but when both arteries were simultaneously compressed the pulsation ceased completely. Accordingly the radial and ulnar arteries were both ligatured just above the wrist; catgut was employed for ligature. The pulsation at once ceased. On the second day after the operation pulsation returned. It was controlled by compression of the tumour with a pad and bandage lightly applied, and after a few days ceased completely. The swelling gradually subsided, and the patient was discharged cured three weeks after operation.

CASE 2. *Axillary Aneurysm; Ligature of the Subclavian in the third part; Cure.*—A Hindoo male, aged thirty-eight, a clerk, was admitted on October 22nd, 1883. He stated that he had suffered from syphilis four years previously, but that otherwise he had been invariably healthy. No evidence of the existence of constitutional syphilis was discoverable on a careful examination at the time of admission. The man was also wholly unconscious of having received any strain or injury which could account for the occurrence of the tumour. He first noticed a hard swelling in the axilla about six weeks before admission. It was then as large as a walnut, hard, and painless, and so far as he could remember did not pulsate. It remained stationary and painless for a fortnight after it was first noticed, and then rapidly enlarged. Pain commenced with the increase of size, radiating all round the tumour, darting down the arm, and finally becoming of an intolerable gnawing character in the site of the tumour itself. On admission, a tumour the size of a large orange filled the left axilla. It pulsated visibly, a thrill was perceptible on palpation, and a loud rasping bruit on auscultation. The pulsation was distinctly distensile, and could readily be controlled by compressing the subclavian on the first rib. The anterior and posterior walls of the swelling were hard and dense, but inferiorly a sensation of fluctuation was made out. The shoulder was elevated, and the elbow could not be brought to touch the side. A careful examination failed to elicit evidence of disease in any of the organs, and, in fact, but for the presence of the aneurysm and the suffering caused by it the man was in perfect health. Two days after admission digital compression was applied to the subclavian for thirty minutes, completely controlling the pulsation in the tumour. The pain in the tumour ceased with the cessation of pulsation, but the finger compressing the subclavian caused such suffering that the treatment had to be given up for the time. A hypodermic injection of morphia was then given. On the following morning a second attempt was made to use digital pressure. The patient could not tolerate it, however, for more than a few minutes. Finding that this treatment could not be borne, and a dark blush appearing on the skin in the axilla where the tumour was most thinly covered, it was determined to tie the artery next day. Accordingly, on the morning following the subclavian was tied in its third part in the ordinary way. The artery was reached without difficulty; but when exposed its pulsation for a few seconds was so feeble as scarcely to be perceptible to the finger. Catgut carbolised ligature was used, and when the ligature was tied all pulsation at once ceased in the tumour. Five minutes after the operation the fingers had become cold, while the shoulder felt abnormally hot. Half an hour later the whole arm and fingers had regained heat, and throughout the day remained distinctly hotter than on the sound side of the body. The arm and shoulder were of course wrapped in cotton-wool and laid comfortably on a pillow. The patient recovered rapidly without a single bad symptom. The wound healed by the first intention. A catgut drain was employed. The tumour slowly became smaller and more dense. Pulsation did not reappear in it at any time. Six weeks after the operation the man was discharged at his own request. He was then in perfect health, entirely free from pain, and could use his arm. The tumour had shrunk to about half its original size and was still contracting.

Four months later he reported himself perfectly well.

Note.—It may be of interest to note the method adopted for applying digital pressure in this case. The patient was propped up with pillows and the operator standing behind him grasped the shoulder, the thumb resting on the spine of the scapula and two fingers pressing deeply behind the inner half of the clavicle.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Surgical Section of this Society on April 4th the following living specimens were shown:—Mr. Hayes: Case of Radical Cure of Hernia. Mr. Croly: (1) Excision of the Knee; (2) Excision of the Elbow; (3) Fracture of the Patella, treated by the expectant method. Mr. Lambert H. Ormsby: (1) Case of Diseased Cervical Vertebra in a Child, treated by spinal support and jury-mast; (2) Case of large Cervical Tumour. Dr. C. B. Ball: Patient in whom Radical Cure of Hernia had been effected by torsion of the sac. Mr. A. H. Benson: Cases showing the result of Dianoux's Operation for Entropium.

The PRESIDENT (Mr. Wheeler) read a paper upon two successful cases of Pharyngotomy. The first was that of a man aged forty-five years, who swallowed a threaded needle eye foremost. His efforts to withdraw the needle by pulling the thread only served to embed the point more deeply. He was admitted to the hospital two days after the occurrence. Various attempts at removing the needle having proved unavailing, pharyngotomy was undertaken. An incision was made on the left side of the neck from the body of the os hyoides to the superior margin of the cricoid. The parts were caused to bulge by passing a staff into the mouth and pharynx, and upon the point an incision was made, the opening being then enlarged with the fingers. The needle was found embedded in the tissues. It was exposed by scraping with the finger nail, and by slight traction of the thread and grasping the needle with forceps it was withdrawn. The patient recovered. In the second case a lady had suffered some months from what was supposed to be ordinary sore-throat. On examination, a tumour about the size of a small egg was found situated below the level of the epiglottis on the right side in the sinus pyriformis. The symptoms of obstruction becoming urgent, it was determined to remove the tumour. An incision was made in the line of the right sterno-mastoid muscle from an inch below the angle of the jaw to the level of the upper ring of the trachea. The pharynx was opened by dividing the tissues on the projecting end of a catheter introduced through the mouth, and the wound was enlarged, first by forceps, then by the fingers. The tumour, which sprang from the styloid ligament and process, was removed piecemeal, and was found to be a spindle-celled sarcoma. The patient made a good recovery, but the disease returned in a few months and she succumbed. Mr. Wheeler emphasised the necessity of a free external incision.—Mr. TUFNELL, having seen the two cases,

Digitized by Google

concurred fully in Mr. Wheeler's suggestion as to the feasibility of a large free external incision, the advantage derived from which was most desirable. Nothing could be more satisfactory than the mode of performing the operation and the result. He referred to a case in which Liston extracted a pike-hook from the pharynx of a boy, first by freeing the hook from its attachment, and next by jerking the double ends with a sponge. A needle might be broken in the extraction. — Mr. STORY said the needle could be cut in two, and then extracted by means of magnetised forceps. He instanced a case of a boy who had swallowed a needle. The boy was, on his recommendation, kept on slops in the hope that the needle would work down with the fæces, which it did in a few days.—The PRESIDENT remarked that one case was seldom a guide to another. Early pharyngotomy ought to receive attention.—Mr. FRANKS considered the great point was whether foreign bodies in the pharynx should be removed by an internal or an external operation. Opinion justified the necessity of pharyngotomy in certain cases; but where there were two natural cavities the need of making an unnatural opening was doubtful. In England the question was discussed of opening the thyroid cartilage or the larynx to get at foreign bodies, and the consensus of opinion was against external operation until every effort by natural means had failed. The laryngoscope should be employed, and where a foreign body was seen in the pharynx it could in the majority of cases be easily got out. Laryngotomy should only be used in extreme cases. In most books pharyngotomy was not mentioned, and the reason was that as a general rule the operation was unjustifiable.—Dr. M'ARDLE would confine pharyngotomy to such tumours as Mr. Wheeler had mentioned, but he did not see how a tumour growing from the styloid process could be extracted through the mouth without injuring some of the large vessels.—Mr. THOMSON asked whether the tumour did not spring from parts external to the pharynx altogether. If that were so, there was no occasion to perform pharyngotomy, except for the convenience of putting in the finger to push the tumour upwards.—The PRESIDENT, in reply, said he had attempted to cut the needle in half with forceps, but had not succeeded, though he had the aid of Dr. Haughton and others. Of course he would not perform pharyngotomy where he could remove the tumour through the mouth. Tumours of the pharynx growing from the base of the skull could not be removed through the mouth. The laryngoscope was a great help in diagnosing the exact situation of the needle and the tumour. The wall of the pharynx was outside the tumour.

Dr. M'ARDLE brought forward a case of Stricture of the Rectum, in which linear rectotomy had injured the patient, and dilatation by bougies was ineffective. Having reviewed the various methods of treating intractable stricture, and shown that the mortality after colotomy was as great as that after excision of the rectum, he invited opinion on the method of excision by a musculo-cutaneous perineal flap and retention of the external sphincter, as advocated by Busch of Berlin.—Mr. HAMILTON regarded one operation only as absolutely radical for cancer of the rectum. Linear rectotomy was only a palliative operation, not curative. But he could hardly say the same of colotomy. It was of course palliative, and gave a great deal of comfort. The only radical cure was extirpation of the bowel; but the cases in which that operation could be performed with satisfaction were very few. Where the limit of the disease could be reached with the finger, the rectum might be removed with a fair chance of success.

The SECRETARY, for Surgeon-Major TOBIN, read the particulars of a case of Ununited Fracture of the Femur, which was under treatment in Netley Hospital in February, 1883. The injury was sustained whilst the patient was on active service in Egypt. He was in the mounted infantry, and on Aug. 6th his horse ran away and dashed him against a tree. The injury was first treated by a long Liston's splint. Whilst in hospital he had an attack of enteric fever, which lasted five weeks. About six weeks after the receipt of the injury the splint was removed, but no union was found to have taken place. A MacIntyre's splint was now substituted, and after six weeks a gypsum bandage was applied and left for several weeks. Still no union took place. On the patient's admission into Netley Hospital the shortening was two inches and three-quarters. On May 18th, 1883, the situation of the injury was exposed, and the fracture was found to be a comminuted one. The ligamentous union between the fragments having been divided, the lower fragment was made to protrude, and its upper extremity excised. The lower extremity of the upper fragment was removed by a chain saw, and the two fragments were then wired together. To counteract the tendency to tilting forwards of the upper fragment it was decided to put the leg up at nearly right angles to the body. In carrying out this plan, an ingenious apparatus devised by the author was employed, by which all the necessary requirements were fulfilled. The patient's recovery was uninterrupted, and when the apparatus was removed firm osseous union was found to have taken place. The shortening was two inches and three-quarters. When this shortening was compensated for by a suitable boot, the patient soon learned to walk about with freedom.

Reviews and Notices of Books.

Clinical Lectures on Mental Diseases. By T. S. CLOUSTON, M.D. 8vo, pp. 624. London: J. and A. Churchill. 1883.

Influence of the Mind upon the Body. By Dr. HACK TUKE. Second Edition. Two vols., pp. 335 and 309. London: J. and A. Churchill. 1884.

Insanity considered in its Medico-Legal Relations. By T. R. BUCKHAM, A.M., M.D. 8vo, pp. 250. Philadelphia: Lippincott and Co.

DR. CLOUSTON'S work is without doubt the best clinical book on insanity yet published, and should be of great use to the general practitioner in dealing with insane cases. The author has clearly and interestingly described a large number of varieties of insanity, especially from the point of view of "progress" rather than from that of "state"; and although these varieties have not been exhaustively treated, the consideration of them has been carried far enough for practical purposes; the practical character of the book, indeed, is evidenced in every page. Regret must be expressed, however, that the author should have still further burdened a subject already overloaded with terms. Psychalgia, psychlampica, psychocoma, &c., give rise to a mental feeling which can best be described by the first of the terms quoted. Dr. Clouston follows the rule of writers on mental diseases by inaugurating a new classification. This is founded on symptoms and is divided into states of mental depression, exaltation, regular alternation, fixed delusion, enfeeblement, stupor, defective inhibition, and, lastly, the insane diathesis. He also treats of some nineteen major and fourteen minor varieties of insanity, these varying in value from general paralysis to post-connubial insanity. The relative importance of each of these varieties would probably vary with the experience and attention of each writer; but Dr. Clouston certainly seems to have treated some of these cursorily, as the traumatic, syphilitic, and gouty forms. In a work of so much clinical detail there is difficulty in criticising the special divisions of the subject, but the concluding lecture on medico-legal and medico-social duties calls for especial commendation for clearness, conciseness, and systematic arrangement. The book is embellished by eight plates, of which several are coloured. One of these represents a section of brain in a state of acute mania, showing a degree of irregular vascularity which Dr. Clouston appears to think is more common than the majority of his contemporaries will admit. A second represents the vertex of the brain in general paralysis, and is too pretty to be satisfactorily pathological. That the book is well written is guaranteed by the name of the author, who in furnishing so useful a work to the profession has added to his well-deserved reputation.

Dr. Tuke, in the preface to the first edition, states the object of his work to have been the collecting together and arranging in physiological order the authentic illustrations of the influence of the mind upon the body. In his second preface he further aspires "to lay down and illustrate certain

Digitized by Google

psycho-physical principles which appear clearly recognisable in the light of modern physiology." A careful perusal of this most interesting work will lead to the conviction that the author has very fully carried out his intentions. The facts collected are evidence of extreme care and extensive research, and their arrangement manifests a clear and systematic appreciation of the whole field of psychic phenomena. Exception can rarely be taken to the conclusions drawn, and the author is certainly modest in regarding his work as one merely of collecting and illustrating, for he makes many obscure points plainer and is eminently suggestive on others. The first three parts of the work are respectively devoted to the influence of the intellect, emotions, and will on sensation, the voluntary and involuntary muscles, and the organic functions. The author concludes that the sensorium *may* be placed in exactly the same condition by a vivid idea as by a sensible object; and that an *emotion*, which by its character or suddenness depresses the activity of the controlling power of the cerebrum, may allow of irregular or excessive action of the encephalic, spinal, or sympathetic nerve-centres. The fourth part is devoted to the influence of the mind on the body in the cure of disease; and Dr. Tuke maintains that there is ample evidence, from the examples quoted, of the therapeutic influences, of expectation, faith, and the concentration of the attention on the seat of the disease. Although the work is so extensively a compilation of facts as to render topical criticism difficult, it is interesting throughout, and will form a valuable and useful book of reference on the subjects treated for many years to come.

Dr. Buckham claims to have written his book with the view of helping to remove the uncertainty of verdicts in insanity trials, but doubt must be expressed in regard to the amount of success which will attend his effort. The introductory chapter gives a useful summary of the various "Judges' opinions" that have been delivered in this country and America; these are of the most contradictory character, and serve only to prove how far are the best legal minds from grasping the subject. The author arrives at the following definition of insanity—viz, "A diseased or disordered condition, or malformation, of the physical organs through which the mind receives impressions, or manifests its operations, by which the will and judgment are impaired and the conduct rendered irrational." Hence the conclusion is deduced that "insanity being the result of physical disease, *it is a matter of fact*, to be determined by medical experts; not a matter of law, to be decided by legal tests and maxims." A lengthy chapter is devoted to the definition of what qualifications should be possessed by an expert, and in deprecating the system by which practitioners who have but little experience of insanity are often called on to discharge the function of experts. The book is well written, and deserves commendation for the clearness with which the author's views are expressed.

A Text-Book of Pathological Anatomy and Pathogenesis. By ERNST ZIEGLER, Professor of Pathology and Anatomy in the University of Tübingen. Translated and edited by DONALD MACALISTER, M.A., M.B. Part II.: Special Pathological Anatomy. Sections 1 to 8. London: Macmillan and Co. 1884.

Manual of Pathological Histology. By CORNIL and RANVIER. Second Edition, re-edited and enlarged. Translated by A. M. HART. Vol. II.: Special Pathological Histology. Part I. London: Smith, Elder, and Co. 1884.

WE are glad to welcome further instalments of the English editions of two well known and much esteemed foreign works,—works which differ somewhat in their scope and in their manner of treatment, but which, dealing with the same subject, may appropriately be considered together. We think that the respective editors have done wisely in not waiting until the original text of the book is completed before submitting their excellent translations to the notice of English students. In the case of Professor Ziegler's work the delay in its completion is really due to the remarkable popularity it has attained, for the author has had to prepare new editions of the first portions before he has had time to publish the final sections; whilst to the painstaking care with which MM. Cornil and Ranvier are revising their "Pathological Histology" may doubtless be ascribed the non-completion of the book.

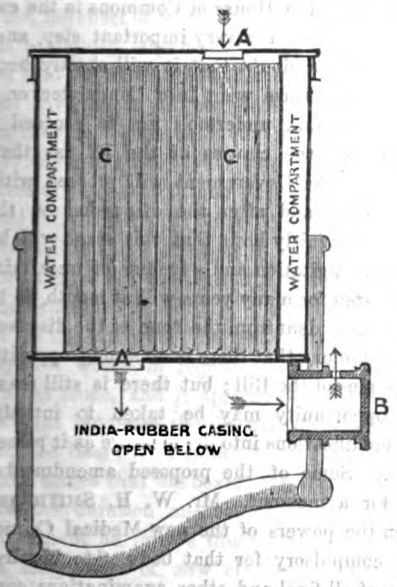
Each of these books has its distinctive characters. That of Ziegler aims at presenting a complete but concise survey of pathological science in its most recent developments; that of MM. Cornil and Ranvier penetrates more deeply into the subject, and bears on every page the stamp of practical personal investigation. Each has its place; for although the first-named is perhaps more particularly suited for class purposes, yet the advanced student will find in both ample material for guidance and instruction. The subjects dealt with in the eight sections of Ziegler's work include (1) the blood and lymph, (2) the vascular mechanism, (3) the spleen and lymphatic glands, (4) serous membranes, (5) the skin, (6) mucous membranes, (7) alimentary tract, and (8) liver and pancreas. The chapters in Cornil and Ranvier's volume are confined to the respiratory organs and the alimentary tract.

If we were to direct attention to any part of the first-named volume as more to be commended than the rest, it would be the pages devoted to the pathological anatomy of the skin, which strike us as conveying in a clearer manner than usual the essential nature of its various lesions. But where all is so good it is invidious to select a part, and we must be contented with recommending the work as in every respect well suited to its purpose. The illustrations, be it added, are of the same high order and finish as those of the former volume. Turning to the French work, the chapters which will engage most attention are undoubtedly those dealing with the anatomy of phthisis. The position assumed by the authors is that of the "unity" of phthisis—i.e., its general underlying tubercular character; but it would seem that they regard more strictly than many who now adopt this, the original view of Laennec, the secondary character of the concomitant inflammatory lesions. Tuberculosis is indeed the great battle-ground of pathologists; and the present volume contains many facts worthy of remembrance with respect to it.

Rupture of the Urinary Bladder. Based on the Records of more than 300 Cases of the Affection. By WALTER RIVINGTON, F.R.C.S., B.A., M.B. and M.S., President of the Hunterian Society, Surgeon to the London Hospital, &c. London: J. and A. Churchill. 1884.

THIS brochure of some 160 closely printed large octavo pages embodies the results of considerable research, and is a really valuable addition to surgical literature. Mr. Rivington has expressed his views on rupture of the bladder in our columns, and this book is indeed but an expansion of those articles. It is a careful and close criticism of all the published cases the author has been able to meet with, and contains most valuable information on the etiology, symptomatology, and diagnosis of this accident. The author does not believe that the evidence in support of the supposed cases of recovery from intraperitoneal rupture of the bladder is sufficient in any one of the cases. So far as regards treatment, he advocates an early resort to bold measures, laparotomy with thorough cleansing of the peritoneal cavity, and then drainage of the bladder through a perineal incision, with or without suture of the original wound of the bladder. While we can only praise the author's work, we must speak otherwise of the publisher's. The book is so closely printed and a large part of it is in such small type, that to read it

Digitized by Google



becomes a most unwelcome labour; while in the copy sent to us a list of the author's published writings is bound up between the text and the index—a most inconvenient and improper place for such an advertisement. We trust that no one will follow the example set either by the form or the position of this remarkable intercalation.

New Invention.

A NEW INHALER FOR THE ADMINISTRATION OF ETHER.

Of the two anæsthetics, chloroform and ether, the former is the one which in Scotland is almost universally preferred. By its use anæsthesia is easily produced, and that with no more apparatus than is afforded by a tolerably thick towel. Ether, on the other hand, is associated in men's minds with difficulty of administration, and with the employment of a more or less complicated and expensive apparatus, requiring the skill of a professed anæsthetist, and it is accordingly shunned by all except a few, who, like myself, thoroughly believe in its superior safety over its younger rival. With the view of facilitating and rendering more general the administration of ether, I have for the past two years been endeavouring to devise an effective apparatus which should be not only safe in use and simple in action, but also economical of the anæsthesia, and I have at last succeeded in the construction of an inhaler possessing these qualifications, and, in addition, capable of producing anæsthesia in a short space of time.

A reference to the accompanying woodcut will show that the inhaler is composed of two parts: the upper designed

Vertical Section of Inhaler.
A, Respiratory valves. B, Expiratory valve. C, Convolutions of bandage.

for the admission of air and for the reception and evaporation of ether, and the lower for application to the face of the patient. The upper or ether division is constructed of nickel-plated metal, and consists (1) of a double-walled compartment adapted for containing a quantity of hot water to aid in the evaporation of ether; (2) a central space (surrounded by the preceding water-jacket) completely filled by a metal frame, on which are stretched convolutions of bandage, for the absorption of the anæsthetic; (3) a movable lid, fitted with an inspiratory valve; and (4) an immovable floor similarly provided. The lower or respiratory division of the inhaler is made of red rubber. Above, it is in close contact with, and encircles, the lower part of the ether division, while below, it is shaped for adaptation to the face. It is furnished with an expiratory valve. From the above description, it will be gathered that inspiration opens the inspiratory valves, whereby the patient is made to breathe air heavily charged in its passage through the ether chamber with the vapour of ether, while expiration closes them, the expired air escaping through the valve constructed for that purpose. It has always been my practice, previous to administering ether, to dull the sensibility of the respiratory mucous membrane by allowing the patient to inhale for about two minutes a few minims of chloroform dropped on a single fold of towel, and then to supply the ether by the apparatus in the following manner. The water-jacket having been filled with tolerably hot water, the lid of the inhaler is removed, and about two drachms of ether sprinkled on the bandage. The lid is then replaced, and the apparatus closely fitted to the patient's face, great care being taken to apply it so exactly that on inspiration all air passes through the ether chamber before reaching the patient's lungs. In about half a minute a larger quantity of ether (half an ounce) is added, and similar quantities repeated, if necessary, until the patient is in a fit state for operation. Generally in from three to five minutes from the commencement of the inhalation of ether, anæsthesia is complete, and it can then be easily maintained by much smaller doses of the anæsthetic. I have used the inhaler in this way in many operations varying greatly in severity and duration, and it has always acted to my satisfaction. Certainly some patients were more difficult to manage than others; but on the whole I have had little trouble from what have been termed the inconveniences of ether, and none at all from the anxious symptoms so commonly observed during the administration of chloroform. In a few patients the ordinary face piece will prove somewhat large; and to obviate this inconvenience each inhaler will be provided with an additional face-piece rather smaller than that which is generally required. Towards the end of long operations the water in the jacket gets nearly, if not quite, cold; but this loss of temperature I have not found to be of any practical moment, the warmth being chiefly necessary at the commencement of anæsthesia, not after its establishment. Indeed, in very hot weather in this country, or in warm climates, I believe that hot water might be dispensed with altogether.

In bringing my inhaler before the notice of the profession, I wish to direct attention to the following advantages which it possesses:—1. Safety: The patient is made to breathe pure air mixed with the vapour of ether, and he never again inspires his own expired air. 2. Economy: He does not waste the anæsthetic by expiring through the bandage. Dissipation of ether is also controlled by the use of the lid, which acts in addition as a protection to the bandage from the wetting effects of antiseptic spray. 3. Simplicity: The inhaler is simple and self-acting, and the ether may be supplied without removing the apparatus from the patient's face. 4. Efficiency: Anæsthesia is easily and quickly induced, often before the surgeon has completed his preliminary antiseptic precautions, and it is effectually maintained. The inhaler has been constructed by Messrs. Krohne and Sesemann, London, to whom my thanks are due for various suggestions and for assistance in points of practical detail.

P. BLAIKIE SMITH, M.D.,
Anæsthetist Royal Infirmary, Aberdeen.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

To the Editor of THE LANCET.

SIR,—Will you permit me through your columns to announce that a general meeting of this Association will be held in Belfast during the meeting of the British Medical Association in that city, at a place and date hereafter to be decided on; and as it is my intention to comment on the deficiencies of Poor-law medical relief in the three kingdoms with the view to their mitigation or removal, I shall be obliged if Poor-law medical officers in England, dispensary officers in Ireland, and parochial medical officers in Scotland will forward to me a statement as to the grievances of which they have reason to complain, so that I might bring them before the meeting, especially instances where extra fees or superannuation allowances have been refused.

I am, Sir, yours obediently,

JOS. ROGERS,
Chairman of the Poor-law Medical Officers' Association.

33, Soho-square, July 2nd, 1884.

THE LANCET.

LONDON: SATURDAY, JULY 5, 1884.

WHATEVER may have been the personal predilections of individual voters, the general result of the election of members of Council of the Royal College of Surgeons of England held last Thursday, cannot fail to give satisfaction. Though the test question put before the candidates was that of Collegiate reform, the election itself did not provoke so much excitement as some of its predecessors intrinsically less important. The principles for which a large number of the more active and spirited Fellows and Members have so long contended were practically accepted by every one of the nine candidates; hence the interest lay chiefly in the selection of the five candidates who would be most likely to give these principles effect within the Council. The choice has fallen on Mr. THOMAS SMITH, who has been re-elected, Mr. GEORGE LAWSON, Mr. A. E. DURHAM, Mr. BERKELEY HILL and Mr. WILLIAM ALLINGHAM. Every one of these gentlemen, either by his conduct in public affairs or by tacit understanding or explicit promise, is pledged to advocate a readjustment of the relations between the Council and the members of the body corporate, whereby the latter shall acquire a larger share in the management of the College. This readjustment a majority of the old Council lately refused even to consider. With the infusion of fresh blood it may be expected a juster and more sagacious view of the situation may be taken. The new members of the Council may be depended upon, as intelligent and honourable men, to join the liberal party within the Council, and to co-operate heartily with its members not only to remedy existing grievances, but also to conciliate the Fellows and Members, and enlist their active sympathy and participation in everything that concerns the welfare of the College. It may be hoped, too, that the obstructives themselves may accept this opportunity to retrace their steps and amend their ways. Only in this manner can they save their reputation for political capacity. We do not expect unanimity. The subject of reform is large enough to permit of many differences of opinion. Even those who are agreed that some changes are needed to put the College in harmony with the demands and requirements of the time are not on all points unanimous as to the nature or precise directions in which these changes should be made. But obstinately to deny the necessity for any change whatever, or wilfully to refuse it, denotes a singular inaptitude for political problems or an inexcusable ignorance of the teachings of constitutional history. Continuity of reforms is an indispensable condition of every active and healthy community. Increase of intelligence and education necessitates extension of political power. If this is true of the general community, how much more applicable is it to a constituency composed exclusively of members of a learned profession.

The Council cannot any longer plead ignorance of the opinions of the Fellows and Members of the College respecting this subject of reform. Two Associations, one of Fellows the other of Members, are engaged in preparing schemes of reform. These schemes will doubtless soon be ready for presentation to the Council. Whatever may be their details, it may be taken for granted that their general tenour will be the reaffirmation of the principles expressed in the recommendations adopted at the general meeting of Fellows and Members held in the College on March 24th last. When the wishes of the Fellows and Members are formally brought to the notice of the Council, the old tactics of unreasoned and unreasoning resistance will have to be abandoned. Writing more than a century ago on a question of Parliamentary reform, EDMUND BURKE said, "I most heartily wish that the deliberate sense of the kingdom on this great subject should be known. When it is known, it *must* be prevalent. It would be dreadful indeed if there was any power in the nation capable of resisting its unanimous desire, or even the desire of any very great and decided majority of the people. The people may be deceived in their choice of an object. But I can scarcely conceive any choice they can make to be so very mischievous as the existence of any human force capable of resisting it." The same arguments may be used with respect to the relations of the Fellows and Members of the College of Surgeons to the Council. The desideratum just now is a majority within the Council amenable to such arguments.

WE were able to announce in our second edition last week that the Medical Act Amendment Bill had passed its second reading in the House of Commons in the early hours of Friday last. This is a very important step, and there is now no reasonable doubt that it will shortly become law. On Monday the House went into Committee on the Bill, but Mr. MUNDELLA undertook not to proceed with the consideration of the clauses of the Bill at that sitting. We trust that the Government will proceed with it on a very early day, and after the discussion on the second reading we may fairly hope that this stage will be quickly passed, and an agitation and a feeling of uncertainty which have now lasted for many years will at length be brought to a close. It is evident from the tone of the discussion in the House of Commons that there is no strong opposition to the main principles of the Bill; but there is still reason to fear lest the opportunity may be taken to introduce some injurious modifications into the measure as it passes through Committee. Some of the proposed amendments we may consider for a moment. Mr. W. H. SMITH proposes to strengthen the powers of the new Medical Council, and to make it compulsory for that body "to inquire into the sufficiency of all final and other examinations conducted or recognised for the purpose of this Act." This is a proposal with which in principle we are in full sympathy, for we are convinced that a system of thorough inspection of all medical examinations by the stronger Council this Bill creates cannot but be good, although the details of the procedure may require fuller consideration. Colonel KING-HARMAN, by two amendments, seeks to introduce compulsory affiliation with "the medical authorities," for he proposes to compel a student to be "attached from the commencement of his professional studies to one or more of the medical authorities," and to pass "therein the esting or sessional examinations required by the Act"; and he further suggests that before being allowed

Digitized by Google

to offer himself for final examination, and after having been admitted as a medical student, he must "thereupon have attached himself to one or more of the medical authorities represented on a medical board." This we trust will not be carried. It is opposed to the principle of liberty. Students should be free to obtain their education where it is best provided without any unnecessary restrictions, the State ensuring that there is a reasonable guarantee of their proficiency to practise before they are allowed to register as qualified practitioners. To seek to bolster up or support existing "medical authorities" by compelling students to connect themselves with them will not secure either that these "authorities" shall fulfil their responsibilities or that the students shall be better educated. If the legal restraint is found to be irksome, it will be thrown off; while if the connexion is of real value, students will not be slow to avail themselves of it. Then we have a series of amendments standing in the names of Mr. WEBSTER and Mr. JAMES CAMPBELL, to add a nineteenth member to the Medical Council by giving the Medical Board of Scotland power to elect three instead of two members, and at the same time to add to that Board two more members, by giving the Universities of Glasgow and Aberdeen one additional representative to be elected alternately by either, and to give the College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow two representatives each in place of three between them, the effect of which would be to give the Scotch corporations a slightly larger proportion of representation as compared with the universities than they have at present. We hope the Government will not yield on this point, for in our opinion they have gone quite far enough in this direction already, although there would be no serious dislocation of the balance of power were these suggestions to be carried out. Colonel KING-HARMAN, however, proposes to add to each Divisional Board the members of the Medical Council "elected for such part of the United Kingdom by the registered medical practitioners therein." This is quite a different matter, and we think it would be well to try how the representative system works in regard to the Council before giving it a wider scope, and it appears to be unnecessary in view of the great influence the Council will have over the operations of the Boards. Colonel KING-HARMAN further seeks to add a clause that the boards shall fix a "minimum standard for the duration and course of study"; but by another amendment he throws this duty upon the Council. By a long series of new clauses the hon. member proposes that upon the Medical Council instead of upon the Boards shall devolve the duty of framing all the rules and regulations for the conduct of the examinations to be held in each division of the kingdom, as well as the conditions of admission as medical students. This would be a very serious alteration in the principle of the measure, which we trust the Government will resist; it would deprive the boards of their chief duties, and would throw upon the Council a large amount of arrangement of details which would be far better managed by local bodies. The only other amendment that we need now mention is one by which Colonel KING-HARMAN seeks to apportion the surplus funds to be expended upon the maintenance of libraries and museums "in proportion to the number of persons who have, during the preceding year, passed the final examination of the Divisional Board therein." This introduces a mischievous spirit of rivalry between the boards of the three divisions of the kingdom, and in its most potent form. We would urge the Government to resist this proposal, and to leave in the hands of the Council, subject to the control of the Privy Council, the apportioning of the surplus funds at its disposal. It is with great pleasure that we are able to write of this measure having reached so advanced a stage; and we trust that, while all reasonable suggestions will be generously considered by the Government, they will steadfastly resist all proposals which would tend to interfere with its efficient working.

THE misleading and delusive endorsement afforded by the Patent Medicines Stamp to nostrums and "specifics" is a subject at the present moment exciting much interest. The Stamp Act was passed in the year 1812, when pharmacy occupied a position far different from that which it has since assumed. Many of our most active drugs—quinine, atropine, and morphia, for example—had not been discovered, and of others very little was known. A perusal of the Act and of the accompanying schedule of the nostrums then in vogue will show what great changes have taken place, and that the Act does not comprehend in any way the present state of medicine and pharmacy. While the Government stamp is understood by the public to convey authoritative endorsement of patent medicines, the law is so loosely worded as to class in the same category with quack medicines legitimate chemical and pharmaceutical preparations, which are only used by medical men, for whom alone they are specially prepared. One of the clauses of this peculiar and incomprehensible Act is that all medicines manufactured out of the country are liable to stamp duty, except only crude drugs. Any alkaloid, extract, syrup, tincture, or any prepared or manufactured medicine, in whatever form, not made in this country, is claimed to be liable. The practical result of this, if interpreted literally, will be not only to put a stop to all original pharmacological research, but to close half the dispensing establishments in the country. Many of our most valued alkaloids and active principles are obtained from abroad, and if these are to come under the ban we are practically precluded from using them, and they will be forced into the category of patent medicines. Every practical medical man knows that many preparations are inert unless manufactured from fresh drugs, and as many of these are plants of tropical origin, which cannot be cultivated in our changeable climate, they will have to be expunged from our list of remedial agents.

There is at the present moment a wide and deep-rooted feeling of dissatisfaction amongst members of the medical profession at the action of the Board of Inland Revenue in endeavouring to enforce in a harsh and arbitrary manner what they conceive to be the provisions of the Patent Medicines Stamp Act. This is no new law; it has been in existence for more than half a century, and it might reasonably be supposed that sufficient time had elapsed to enable the legal advisers of the Crown to come to some definite conclusion as to the nature of its enactments and stipulations. This, however, appears not to be the case, and we learn that

Digitized by Google

it has been officially intimated that the clauses of the Act are in future to be literally interpreted, and that they will be strictly enforced. To this no reasonable objection could be entertained if the Act had only been so worded as to afford some indication of the intentions of the original proposer; but, unfortunately, it is so vaguely drafted and badly drawn, and displays such ignorance of technical details, that it may be interpreted to mean almost anything. Probably it was designed to check or suppress the ever-increasing sale of quack medicines; but if such were the intention, it must be admitted that it has signally failed. The patent medicine proprietor, so far from objecting to the Act or wishing it repealed, is decidedly anxious for its retention, for it serves him as an excellent advertisement. It is a well-known fact that many people believe that the presence of the stamp is an indication that the medicine has been examined and found pure, whilst others consider that it has received a Government endorsement of its curative properties. This idea is encouraged in every way, in proof of which we have only to refer to the handbills and wrappers which accompany most of these medicines. For example, it is stated that, "to guard against fraud, the Commissioners of Inland Revenue have caused the name of the proprietor to be engraved on the Government stamp affixed to the bottle," whilst in some cases it is asserted that Her Majesty's Commissioners of Stamps have permitted the name to be engraved on the stamp "*to protect the public from imitations of this medicine.*" Another reason why the maintenance of the Stamp Act is favoured by the patent medicine proprietors is that they make as large a profit on the stamp as they do on the medicine. In estimating the original cost of the nostrum the price of the stamp is always included, the calculation of profit being based not only on the materials, bottles, labels, and labour, but also on the cost of the Government stamp itself. A profit on the stamp is again added by each vendor through whose hands the nostrum passes until it reaches the consumer. The result of these accumulating profits is that instead of the consumer paying simply the amount fixed by Government for the stamp, which is supposed to be based on the retail selling price and to amount on an average to 17½ per cent., he pays its cost several times over. For example, in the case of a bottle of medicine selling at 4*s.* 6*d*, the original cost of the material, bottle, label, and labour would certainly not exceed 1*s.*, or, adding the value of the stamp, 1*s.* 6*d.* The manufacturer would get for this not less than 2*s.* 10*d.*, for patent medicine manufacturers expect usually to clear not less than 100 per cent. profit; the wholesale dealer, with the usual wholesale profit of 10 per cent., would get 3*s.* 2*d.*; and the retailer, with the usual retailer's profit of 30 per cent., would get 4*s.* 6*d.* This 6*d.* added to the 4*s.* is generally supposed by the public to cover the cost of the stamp to them, but if this stamp were not reckoned as part of the outlay the original cost to the manufacturer would be 1*s.* instead of 1*s.* 6*d.*, a difference of 50 per cent.; the same percentage of profit being added, the wholesale dealer would pay 1*s.* 7*d.*, the retailer 1*s.* 9*d.*, and the consumer 2*s.* 6*d.* It will be seen that the manufacturer not only in no way suffers, but, on the contrary, makes a handsome profit on the stamp, in addition to securing a Government endorsement, which is of the utmost value to him; whilst the consumer is not only enticed into purchasing a possibly worthless nostrum at an enormous profit to the vendor, but is mulcted several times the cost of the stamp. The injurious effect on the national health of taking these medicines is incalculable.

It cannot be the wish of the Administration to give the endorsement the stamp affords to patent medicines. If the Government feel the need of this source of revenue—which amounts to £150,000 per annum,—it can be very little satisfaction to them to know that, while pretending to tax the manufacturer of patent medicines, they are really putting a profit in his pocket and heavily taxing the sick, who are thus liable to be deluded into confiding in quack remedies by the apparent endorsement of Her Majesty's Government. The existence of such an anomalous state of affairs is no longer possible. It is a matter of vital importance, and affects so critically the health and well-being of the nation that not a moment should be lost in agitating for the immediate repeal of the Act.

SINCE our last issue all doubt as to the true character of the cholera outbreak in the south of France must be regarded as having passed away, and this notwithstanding Dr. FAUVEL'S characteristic persistence in viewing cholera in his own country as a very different thing from the same disease in India, Egypt, and elsewhere. True cholera has prevailed in Toulon; it has spread to Marseilles and to several other places; and the countries which with France advocate stringent quarantine measures have, to the great annoyance of many eminent Frenchmen, put France in quarantine. So far no satisfactory history of the origin of the epidemic has been forthcoming, and the efforts which were made to keep the whole thing secret, do not augur well for procuring precise information on the point. But, so far as we can judge, the case seems to be one of cholera first appearing on board ship in the Eastern seas, of the poison being retained in and about the vessel notwithstanding certain measures of disinfection, and ultimately of the importation of the infection on land by means either of the crew, or of the soldiers, or of the persons appointed to cleanse the vessel, and who were probably suffering from an infectious form of diarrhœa, which either escaped notice altogether, or was not regarded as of sufficient gravity to warrant the publicity which adequate measures of precaution would have involved. This may have been regarded as good policy, but it is not quarantine. Fortunately the disease is not making headway by means of those sudden and alarming bursts which so frequently characterise the course of cholera; but too much trust must not be placed on this aspect of the outbreak, for even if Toulon and Marseilles find themselves able successfully to combat the disease, there is no knowing to what other places it may be, or has already been, imported, nor how far such localities may be able to withstand its epidemic spread.

It therefore becomes important for us in this country to take stock of the measures of prevention which we possess. Under the Order of the Local Government Board, July 12th, 1883, all vessel arriving within the districts of port sani-

Digitized by Google

tary authorities will be visited by an officer of customs; and if the report given to him is such as to afford grounds for suspicion, he has power to detain the vessel and all on board for a period of twelve hours, in order that he may communicate with the medical officer of health of the port. The vessel having been moored or anchored at a suitable place will be inspected by the latter officer, who will satisfy himself as to the health of crew and passengers, and no person may leave the ship until the necessary examination has been made. If all be well, the vessel will be no longer detained. If, on the contrary, any cases of cholera or of choleraic diarrhœa be found, then the medical officer of health will certify accordingly; all the sick may be removed to such hospital as has been appointed for the purpose, or the ship itself may remain subject to the control of the medical officer of health. Persons whose cases are suspicious only may be detained on board for a period not exceeding two days, to be dealt with according to the result at the expiration of that time. At the earliest stage, and at all subsequent stages, of the examination, all persons who are certified to be in health will be allowed to land immediately on giving their names and the places of their destination. The dead are to be buried at sea, or in certain instances, and then subject to the regulations laid down by the medical officer of health, on land. The ship, and all articles of clothing or of other personal use which are likely to retain infection, must be disinfected either by the master of the vessel or, failing him, by the sanitary authority.

Under these circumstances, the arrangements for ascertaining whether any dangerous disease is on board a ship may be regarded as sufficient, and the measures of inspection and isolation which will be carried out should afford a very considerable amount of security. But with the short sea-passage between England and France, it is impossible to say that we run no risk, and hence we may have to trust as fully to our land organisation as to the port sanitary system. But here, again, it is on inspection and isolation that we must rely, and having regard to the comparatively few channels by which the infection of cholera tends to spread, we believe that we may do so far more effectively than by trusting to any such system as quarantine and sanitary cordons. In the metropolis the Diseases Prevention (Metropolis) Act of 1883 provides us at once with a large amount of hospital provision, and throughout the kingdom sanitary authorities have been empowered ever since 1866 to protect their districts by the erection of isolation hospitals for infectious diseases. If they have failed to do so, and cholera comes upon them unexpectedly, it is they who will be to blame, and not the system on which England has decided to trust ever since the Vienna Conference some twenty years ago. The operation of that system was [illegible] a few months back when H.M.S. *Crocodile* [illegible] history of cholera. She was detained by the [illegible], the medical authorities inspected the troops and crew she carried, the healthy were allowed to land, and [illegible] convalescents were detained in one or other of the [illegible] which had been held in readiness to receive such [illegible]. On this system, coupled with [illegible] or [illegible], streets, sewers, and water-supplies, we shall have to trust whether [illegible] of cholera comes to us from France, Egypt, or India, and with the genuine co-operation of port, urban, and rural sanitary authorities we may expect to occupy a fairly strong position of defence.

Annotations.

"Ne quid nimis."

THE COLLEGE ELECTION.

ON Thursday last the election of members of Council of the Royal College of Surgeons was held in the Library of the College. The result was as follows:—

Mr. LAWSON	158,	including	2	plumpers.
Mr. DURHAM	154	,,	8	,,
Mr. T. SMITH	152	,,	6	,,
Mr. BERKELEY HILL	127	,,	3	,,
Mr. ALLINGHAM	108	,,	8	,,
Mr. Pemberton	103	,,	6	,,
Mr. Gant	77	,,	2	,,
Mr. Cowell	55	,,	5	,,
Mr. Barwell	51	,,	1	,,

Mr. T. Smith was therefore re-elected, and Messrs. Lawson, Durham, Berkeley Hill, and Allingham were elected members of the Council. Two hundred and seventy-seven Fellows voted, but five voting papers were invalidated through informality.

VACCINATION IN THE METROPOLIS.

DR. CAMERON'S proposal, if we understand him correctly, to transfer from the boards of guardians to the thirty-nine metropolitan sanitary authorities the administration of the Vaccination Acts would not, we fear, be of any material assistance in preventing the spread of small-pox. We can fully sympathise with his desire to have so important a means of preventing disease entirely separated from the administration of relief to the poor; but as at present constituted, the metropolitan sanitary authorities could hardly be entrusted with this duty. It must be remembered moreover that arrangements of a very complete character can now be made in all parts of London for ensuring the vaccination and revaccination of all persons applying at the vaccination stations as well as for the performance of this operation in houses in which a case of small-pox occurs. The removal of the sick to the hospitals of the Metropolitan Asylums Board is always preceded by the visit of the district medical officer, who is permitted to charge for the vaccination, and, with certain age limitations, for the revaccination of all persons who are insufficiently protected against small-pox; or arrangements may be made with the public vaccinator for this purpose. In practice the restrictions with regard to age would not be too closely adhered to for those persons who are absolutely exposed to small-pox infection. For all other persons than those who are resident in a house with a person suffering from small-pox, it is far better that they should attend at the public vaccination station, where the operation can be more effectually performed without resort being had to stored lymph. Dr. Cameron's demand for a more general use of lymph from the calf would only have weight if arm-to-arm vaccination were not a satisfactory method of affording protection against small-pox. It should be understood that arm-to-arm vaccination is far more protective than the use of stored lymph, whether it be human or animal. Although, therefore, there is room for the use of animal lymph in giving opportunity to public vaccinators to begin their operations, it is impossible that it should entirely replace the proper use of humanised lymph, upon which the protection of the community must depend.

SCIENTIFIC ASPECTS OF THE HEALTH EXHIBITION.

THE two scientific laboratories which have just been opened under the superintendence of Mr. Watson Cheyne and Professor Corfield must prove highly attractive to the medical profession and men of science generally. The biological laboratory, which has been arranged by Mr. Watson Cheyne, is on the top floor at the southern end of the City and Guilds Central Institute in the Exhibition-road. This institute is now part of the Exhibition, and can be entered either from the Exhibition-road or from the eastern corridor of the Exhibition itself. In his laboratory Mr. Cheyne has arranged a number of preparations intended to show the methods and the results of the work which is mainly associated with the names of Pasteur and Koch. The methods of preparing cultivating media, and the results of cultivations, are here shown, and many a visitor will be surprised to find that although micrococci and bacilli are amongst the most minute of microscopic objects, their mode of growth in cultivating media is often characteristic and easily recognisable to the naked eye. The organisms associated with typhoid, glanders, pneumonia, erysipelas, osteo-myelitis, anthrax, chicken cholera, and other zymotic diseases may all be seen in process of growth, as well as many other organisms which are not pathologic, and others which are pathologic to animals rather than to man. The diseases of the vegetable as well as of the animal kingdom will form the subject of demonstration in this room, and we may add that Mr. Cheyne purposes giving demonstrations, especially intended for members of the medical profession, on Thursday afternoons at 4 P.M. Professor Corfield's laboratory is on the ground floor, in a special building situate at the rear of the City and Guilds Institute. This laboratory will prove attractive to public analysts, medical officers of health, and chemists generally. The laboratory has been fitted with great completeness, and is furnished with all that is necessary for the most searching analytical processes. Assistants will always be on duty in these laboratories, and will be glad to offer any explanation; but we may add that Prof. Corfield has arranged for a series of special demonstrations on Friday afternoons at 4 P.M. Those who are interested in questions of pure science should not fail to visit the French Court and inspect the material which has been sent from M. Pasteur's laboratory, and the various articles from the observatory of Mont Souris which have been contributed by M. Miquel. In Pasteur's exhibit is shown, by means of drawings, &c., the work which this extraordinary man has done in connexion with silkworm disease, anthrax, chicken cholera, and acetous fermentation. The mode of sterilising flasks and of conducting other processes connected with the investigation of organic germs is here objectively and instructively displayed. No one who is at all competent to observe can fail to be deeply impressed by the exhibit of M. Pasteur and with the work which is going on in Mr. Cheyne's laboratory. Many a disbeliever in "germs" will have his scepticism either lessened or removed.

THE LEGALITY OF CREMATION.

ON June 19th, in the Queen's Bench Division, the court for the consideration of Crown cases reserved had before it an important case for decision. The appeal was against a ruling of Mr. Justice Hawkins at the Leeds assizes, that it was illegal to cremate a body when the coroner had determined to hold an inquest upon it. The contention on the part of the Crown was that to prevent a coroner from carrying out a judicial act was an indictable misdemeanor. This was disputed by the defendant's counsel, who argued that the alleged offence was not specified in the statute, that in fact it was unknown to the common law; and further, that in order to constitute an inquest a judicial act it must be shown that the death was due to violence. We are glad to find that the judges were unanimous in confirming the conviction. It would be a most unfortunate thing if the dictates of common sense were overruled by some legal technicality. The functions of a coroner are clearly to find out whether a death was violent or not. The only preliminary condition he has to comply with is that from information supplied to him he shall see reasonable cause for instituting an inquiry, the very object of which is to establish the facts of the case. In the present instance two women, mother and daughter, burnt the body of the illegitimate child of the latter, in the full knowledge that it was intended to hold an inquest upon it. It was not charged against them that the death was caused by violence, but it was proved in evidence that it occurred somewhat suddenly. As Mr. Justice Grove remarked: "If persons having possession of a dead body upon which there were reasonable grounds for the coroner to hold an inquest were to be at liberty to destroy it, and so prevent the inquest, the consequences would be most formidable, and it might tend to give impunity to murder." The point has yet to be determined whether the burning of a body on which the coroner decided to hold an inquest subsequent to the cremation having taken place is illegal or not. Cremation in itself is not an offence in the eyes of the law, but it must not be practised so as to constitute a nuisance, nor in order to interfere with the course of justice. The present case gives emphasis to what we have frequently expressed as a fatal objection to the proposed institution of cremation as a regular and recognised form of the disposal of the dead—viz., that it would put a premium on crime by destroying the evidence on which alone, perhaps, a conviction could be obtained.

CHOLERA AND COWARDICE.

IT is a most deplorable proof of the weakness of human nature that it is at all times prone to fall into a state of panic when brought face to face with the inevitable. We must all die, and we are not ignorant of this our destiny, nevertheless, the instant a danger to life is recognised, we fly from the peril with the impetuous haste of crazy and cowardly creatures, forgetful alike of duty and decency. It is vain to argue in favour of self-possession. Philosophy has no charm for, or power over, the man who impulsively turns his back to the enemy. Nothing we could urge would have the slightest weight with the multitude bent on escaping from the ports and cities which are just now supposed to be rife with the infection of cholera. These flying crowds, on safety all intent, must be left to their own devices. It is manifest that they will spread the malady, and it is scarcely less certain that they will, many at least, lose their lives in trying to save them. With regard to these matters, however, it is useless to speak. Suffice it to point out that, although in the presence of an epidemic of cholera there is always and unquestionably some personal peril of contracting the disease, it is by no means certain that this is increased by remaining in association with the sick, or that the danger is to be avoided by running away! During severe epidemics it has been noticeable that the mortality has not been, by any means, greatest in the very *centre*, so to say, of the disease. In the hospitals and among the cholera patients scattered throughout the population, medical officers and nurses have gone about doing their duty with no greater mortality than that of those who have kept aloof. Indeed, it is probable that a certain amount of immunity from disease has been enjoyed by those who have not feared the danger of infection. The great secret of success in warding off disease is the preservation of health. We mean that if, heedless of danger, men and women do their duty to them-

Digitized by Google

abound them—keeping up a cheerful temper and a trusty spirit, neither abusing the good things of life nor avoiding them; in short, living as all should live, whether in the midst of a healthy population or in the presence of an epidemic—they have a far better chance of escaping disease than by falling into a state of panic and "hastening to leave." The true policy is to kill the germs of disease on the spot, whether they be in the water or in the air. Every particle of the *dejecta* should be destroyed—not simply deodorised, but destroyed by a powerful agent capable of burning up organic material. This should be done at once and instantly on the spot, not merely with the choleraic, but with every patient who may have diarrhœa, whether specific or simple. If this be done, and the general sanitary conditions, and the average health of the community be looked to, there is no peril that need scare anyone out of his or her sober senses in an epidemic of cholera either on the Continent or at home.

THE HEALTH EXHIBITION AND THE HOSPITALS.

It has been rumoured that a grand *fête* is to be given at the Health Exhibition shortly in aid of the London hospitals. We trust that this is a fact, and, if so, congratulate the authorities on their excellent purpose. But visiting the Exhibition the other day, and noticing the vast number of people of all sorts and conditions drawn together by the attractions of "health" and its surroundings, we had it in our mind to go further and to appeal to those who have control of the financial arrangements of the undertaking to employ some of their surplus funds in aid of the battle waged by the hospitals against its terrible, but, alas, inevitable antithesis—"disease." We thought that this might be accomplished either by devoting a week's, or better still a fortnight's, receipts to such a purpose; or that the precedent set by the Fisheries Exhibition—when a large sum from the profits was awarded at its close by the Council for the benefit of the fishing industries—should be followed, and that some of the money so pleasantly and profitably earned and spent respectively in the reception and diffusion of knowledge as to the constitution, conditions, and maintenance of health should be voted to those excellent but, sad to say, necessitous institutions where disease is studied, grappled with, and, happily, oftentimes conquered.

THE ACTION OF DIGITALINE.

M. KAUFFMANN, of Lyons, working in M. Chauveau's laboratory, has studied experimentally the physiological action of digitaline (amorphous), and embodied his results in an interesting paper contributed to the *Revue de Médecine* of May 10th. His experiments are all the more valuable in that they were made upon the higher animals (dog, ass, and horse). He finds that locally digitaline acts as a powerful irritant, which renders it unsuitable for administration by the skin, whether intact or denuded of epidermis, the inflammation excited by the substance preventing absorption. It has similar irritant action on mucous membranes, and the stomach can only tolerate minute quantities. For the same reason, only very dilute solutions (1 in 500 or 1 in 1000) are available for subcutaneous injection. He found that absorption took place most readily by the respiratory mucous membrane, next by the gastro-intestinal, next by connective tissue, and least by muscle—the febrile reaction ensuing on injections into the last two named tissues masking the specific effects of the drug. The results of all his experiments as to the general action of digitaline are partly at variance with accepted teaching, particularly as to its effect on the renal secretion; for he finds that in healthy animals digitaline, whether given in large or small doses, does not produce diuresis. Administered hypodermically or in the form of powder in the stomach, it causes a diminution in the quantity of urine excreted, and an increase in the amount of urea. Given by the stomach in the liquid form and in small doses, it diminishes both the quantity of urine and of urea. It only produces diuresis in dropsies due to disorders of the circulation. Of its physiological action on the circulatory organs he declares that in small doses digitaline slows the pulse, but in larger doses accelerates it; and he attributes the former effect to stimulation of the medullary and intra-cardiac centres of the moderating system, the latter—i.e., acceleration—to central and peripheral paralysis of the same system. The intra-cardiac pressure, both diastolic and systolic, is increased, and also the energy of the cardiac contraction. The action of the heart is more regular when accelerated than when slowed by digitaline, whilst the pulse is stronger with small doses of the drug than with large. Small doses slightly raise arterial tension by central and peripheral stimulation of the vaso-motor nerves; stronger doses at first increase then diminish the tension. The rate of arterial blood-flow is diminished, and the rectal temperature is lowered.

CHILD MORTALITY IN NEW YORK.

THERE are reasons for believing that the mortality statistics for New York are more trustworthy than are those of the majority of American cities, in which the defective system of death registration precludes almost the possibility of accurate or complete statistics. It appears from an official return recently issued that the estimated population of New York in the middle of last year was 1,317,691 persons, and that the deaths recorded during the year were equal to a rate of 25·8 per 1000, while in London the rate did not exceed 20·4. Thus the mortality last year in New York exceeded that in London by more than 26 per cent. Zymotic fatality was nearly twice as great in New York as in London, and the excess in the mortality from diseases of the respiratory organs and phthisis was very marked. It is, however, to the death-rate of children that we would now more especially call attention. Based upon the age proportion of the population of New York at the last census in 1880, it may be estimated that 156,379, or 11·6 per cent., of the population in the middle of last year were children under five years of age; the recorded deaths at those ages were 13,856, and equal to a rate of 90·3 per 1000 living. In London the death-rate last year among children under five years of age did not exceed 65·1 per 1000; the rate of mortality at those ages, therefore, exceeded the rate in London by nearly 39 per cent. The registration of births in New York is confessedly incomplete, and it is therefore impossible to estimate the rate of infant mortality—that is of children under one year of age. The recorded birth-rate in New York in 1883 was only 23 per 1000, and was smaller than the death-rate. The true birth-rate in New York is probably considerably lower than that which prevails in London, but it is undoubtedly higher than the death-rate. It may be noted, moreover, that whereas 13 per cent. of the London population consists of children under five years of age, the proportion of the New York population at these ages does not exceed 11·6 per cent. This deficiency of children in New York was partly due to the low birth-rate, and partly to the high rate of child-mortality. With regard to this excessive rate of mortality among children under five years of age in New York, it appears to be mainly due to the fatality of diarrhœal diseases, from which resulted 2897 of the 13,856 deaths at these ages in 1883, being equal to a rate of 18·9 per 1000 living under five years of age, whereas the mortality from diarrhœal diseases among London children under five years

Digitized by Google

of age did not exceed 4·6 per 1000. After due allowance, however, for this excess of diarrhœal mortality among children, in great measure the result of climatic differences, there still remains a striking excess of child-mortality in New York, most of which may be safely attributed to defective sanitary arrangements.

COVENT GARDEN AGAIN.

THE Duke of Bedford not having been able to dispose of Covent Garden Market to the Corporation of the City of London or any other responsible body, ought clearly to discharge the public duties of ownership, and enforce such regulations as shall convert the place from a nuisance to a convenience. A vegetable, fruit, and flower market should certainly be a pleasant place, not an abomination in the land. The traffic arrangements are scandalously bad, but the police must be left to grapple with that difficulty until the roadway can be opened. It would not be difficult to relieve the neighbourhood of much of the traffic if men were placed at the distant ends of the outlying streets; for example, no cab or carriage ought to be permitted to enter from Long Acre. It is the *cross* traffic that causes the block. Meanwhile, His Grace must be held accountable, by his agent, for the systematic neglect of ordinary cleansing and the prompt removal of offal. We are glad to see that our useful contemporary, *Punch*, has this week returned to the charge against the owner of Mud-Salad Market.

REGULATION OF FEMALE LABOUR.

MANY indications tend to show that the Factory and Workshops Act, never a complete measure, is becoming yearly less capable of compassing its allotted ends. It requires extension in many directions. The pressure of labour on men is sufficiently great, and unchecked by opposing interests, to call for official regulation, which as yet it has not received. The occupations of women were more considerately dealt with when the Act was drawn up. In regard to them, however, there is much to be desired, and it is very evident that in many cases existing means of inspection have been unable to prevent evasion of the statute by employers. Whatever may be said of the equality of the sexes, it must be conceded that such equality, if it exists, is general and not particular. There is marked disparity, for instance, in favour of the male, in physical endurance, and this is not a mere matter of education. Health is a word of different meaning for the two sexes. It is a part of the health of women to suffer pain, and even illness, and suffering more they necessarily work less, or should. Special legislation, then, in the limitation of work, may be claimed for women, seeing that the variable code of business custom takes little heed of physiology. The duration of actual working time allowed by the Act—a maximum of fifty-six hours a week—might well be lessened without unfairness to employers, and with much-needed benefit to their female workers. Even more imperative is it that sanitary principles should be rigidly enforced in business houses. This can only be done by the extension to shops of supervision such as now prevails in factories. There can hardly be any reasonable objection to such a course. Factory inspection has been found to work, on the whole, not less to the satisfaction of master than to the advantage of men. Why should not tact and candour be equally successful in the visitation of shops and warehouses? Here is an opening for the employment of women. If appointed to be inspectors of the condition of their working sisters, they would doubtless bring to bear sufficient skill and knowledge of their duties, with a more penetrating insight into various important details, than a man could be expected to show. One important provision should not be lost sight of. It is that suggested by Dr. J. H. Bridges in an able paper read at the Health Exhibition on June 26th—viz., that women should not be allowed to resume work in cases of confinement until six weeks after that event. This is not too long a period of rest. Perhaps, however, it would be better to make the return to business dependent on a medical certificate of perfect fitness for it. The question of female labour is a very large one. Women themselves have much in their power with regard to it. Let them not forget that united feeling and action among themselves will help to persuade public opinion of their just requirements.

OXYGEN IN CHOLERA.

THE news telegraphed to *The Times* from Toulon on Wednesday last that Dr. Troncin was successfully employing inhalation of oxygen in cases of cholera reminds us of the very various methods which an epidemic brings to light, and of the numerous infallible remedies that are invariably introduced. It is perhaps unfortunate that wider experience is not awaited before a new measure is thus vaunted, for too often the result issues in a disappointment as keen as the hopes raised have been high. From the details as yet to hand, it would appear that the oxygen is employed in the collapse stage, and its alleged good effects may be ascribed to stimulation of the respiratory and cardiac centres. Any therapeutic measure which can avert impending death from collapse is to be welcomed, and doubtless this method will be fairly and fully tried, with, we hope, the success that is anticipated. But any measure in this stage must be regarded as a *dernier ressort*, and the therapeutics of cholera rest mainly in the direction of prophylaxis, careful selection of food, and the treatment of the premonitory diarrhœa.

SANITARY CONDITION OF CALCUTTA.

WE regret to learn by the Indian papers that the measures which were proposed to be carried out immediately for the improvement of the sanitary condition of Calcutta have, by an ill-judged vote of the municipality, been arrested for apparently an indefinite period. It appears that the Government made an offer to reduce the annual contribution of the municipality towards the police tax by a sum of about one and a quarter lakhs of rupees on the condition that for the future one lakh should be spent on "bustee" reclamation and similar sanitary work, in addition to the one and a half already devoted to that purpose. It was ascertained by the Chairman of the Commission that this arrangement could be easily carried out without any increase in the house tax, which had at one time been suggested as necessary, and he accordingly moved that the offer of the Government be at once accepted. The native element in the Commission, however, objected to this, and carried an amendment refusing to accept the proposal of the Government until further representations had been made in the matter. As the *Pioneer* remarks, "This means more delay, more talk, more waste of time, longer postponement of improvements, which are by universal admission becoming every month of more imperative necessity." It is very unsatisfactory to find that one of the results of the introduction of municipal Government into Calcutta is the obstruction, on the false plea of economy, of measures having a most important bearing on public health, more especially of the poor, in that great city. Such short-sighted policy cannot fail to recoil upon the heads of its promoters. We trust that the Lieutenant-Governor, who has shown himself alive to the sanitary requirements of Calcutta, may be able to press on the urgent improvements necessary for the prevention of disease, and that he will withhold the boon he has offered of a reduction in the police tax till he has a guarantee that the saving will not go into the pockets

Digitized by Google

of a few greedy houseowners, but be appropriated in a manner which will benefit the poorer inhabitants, by removing permanent sources of disease from the localities in which they are compelled by circumstances to reside. The mortality of Calcutta during the present year has risen to 40·4 per 1000, in a great measure owing to the prevalence of cholera, "a perfectly legitimate consequence of filth unremoved, and accumulating among the dwellings of the people." The blame of this lies clearly with the municipality, and they seem disposed—or at least a majority of them—to continue such a disgraceful condition of affairs until they are satisfied that their own pecuniary interests shall not be affected by a possible increase of the house-duty. We trust that effectual means may be found to compel the Commissioners to carry out the necessary sanitary works.

CANAL BOAT REGISTRATION.

IN our time and country travelling and traffic are chiefly by road and rail. Older systems have become comparatively unused. Among these the canal-boat still holds its own and works its way from one river and one populous district to another. The boatmen and their families do not form a numerous class, though it is one which is increasing in numbers. It is, moreover, recruited from the poorest of the people. The homes of these persons are necessarily not commodious, and they depend for wholesomeness much more upon their surrounding atmosphere than on their internal arrangements. It is obvious that the public would profit in more ways than one if the law for registration of these craft, which is at present ineffective for want of executive machinery, were put in force. Here and there desultory attempts at notification have done some good. The School Board officers have taken measures to secure the attendance of the boat children, but the canal population, as a whole, have usually been out of sight and out of mind. When we consider the results in propagation of disease, and in hidden development of crime and immorality which may arise from this neglect, we can but hope that it will soon terminate. It cannot be said that the privileges of owners are infringed by the application to their inland barges of conditions to which even the mercantile marine is subject.

IODIDE OF POTASSIUM IN PNEUMONIA.

AGREEING with Schwarz that this disease may be considered not as a "local disease with general symptoms," but as a "general disease with local effects," Dr. Luigi Gualdi of Rome gives the iodide in forty-centigramme doses every two hours, at the same time applying the ice-bag over the seat of pulmonary inflammation (*focolaio pulmonitico*). In thirty-nine cases in which he practised this treatment he had excellent results. In all, without distinction, he observed that the sputum, from being viscid and tenacious, became, before the second day, fluid, resembling bloody serum; that with the cessation of the fever the exhaustion also ceased, although the physical state of the lung was not improved—nay, in some cases aggravated; and, finally, that in all the convalescents the appetite was so sharpened that the ordinary diet had to be considerably increased. The mortality was 6 per cent., while of the two who died one could not be included in the calculation, because, being affected with pneumonia of the apex with furious delirium, he took only two grammes of the iodide of potassium. It is worth remarking, continues Dr. Gualdi, that the fever and the exhaustion ceased, although the physical condition of the lung remained unchanged, thereby confirming Schwarz's position, that the fever is independent of local alterations; also Jürgensen's contention that the cause of the exhaustion resides not in the change in the lung, but in the fever, seems to be similarly confirmed. Dr. Gualdi concludes that from his experience the treatment by the iodide succeeds better with the youth of either sex than with adults; that the iodide should be exhibited at the beginning of the disease, to ensure an immediate and perfect result; that the iodide is efficacious over the fever and the exhaustion, but not over the localisation, which latter indeed may even be extended under the treatment; that the iodide and potassium combined separate in the organism, so that each has its special virtue; and, finally, that the action of the ice is secondary, inasmuch as it operates on the effects, and not on the cause of the disease. It is useful in the congestive stage; hurtful when the contents of the air-cells are already solidified and the lung indurated.

THE CONDITION OF THE BLIND.

THE prevention of blindness and the amelioration of the condition of the blind have respectively been the subject of discussion by the Ophthalmological Society and an influential meeting, with the Duke of Westminster and Mr. Fawcett at its head. With such powerful agencies at work there can be little doubt that the proportion of blind persons will diminish and their state will be rendered less irksome. Mr. Fawcett strongly advocated the retention of the adult blind in the midst of the community from which they derived all the indescribable joys and pleasures of home life. No greater mistake could be made than to group them in large masses. A fundamental distinction ought to be drawn between the young blind and the adult blind. The young blind must, for purposes of education, be drawn together in order that they might have placed at their disposal the special appliances which the education of the blind required. Mr. Fawcett does not seem to have heard of the careful inquiry made by the committee of the Ophthalmological Society. It transpired from this investigation that about 30 per cent. of persons in blind asylums both in England and Germany owe their blindness to preventable causes—i.e., ophthalmia neonatorum.

"LICENSED MANSLAUGHTERERS."

UNDER the above sensational heading "A Country Parson" writes to one of our daily contemporaries making complaint of the alleged inadequacy of the existing authorities to deal with cases of what may collectively be termed professional malpractice. The writer speaks of the creation of a tribunal who might safely be entrusted with a jurisdiction similar to that exercised by the Incorporated Law Society in the case of peccant solicitors. We are not amongst those who believe that the existing machinery for the guidance of the medical profession is the best possible which could be had. But it is not with this aspect of a country parson's letter that we would at present deal. He has dubbed one of his townsmen an "ignorant young fellow," and, what is worse, accused him of manslaughter on grounds the adequacy of which does not commend itself to the impartial mind. We must speak cautiously because the facts of the case have been so briefly set forth. A certificate was given by the medical attendant that a child had died of typhoid fever, with perforation of the bowel. "Only the other day a child in my schools died somewhat suddenly in convulsions, after four days' illness," writes the country parson. Notwithstanding that so little is said of the nature of the child's disease, yet, to our minds, there is no inherent improbability in the cause of death assigned by the "ignorant young fellow." It is stock-knowledge with every medical man that a patient may be the subject of typhoid fever without experiencing enough sense of illness or other symptoms of the malady to lay him up. Again, it is well known that perforation of the intestines and death may come on in the course of what Murchison has called the "ambulatory"

Digitized by Google

form of pythogenic fever. "A Country Parson" probably owes his knowledge of medicine or, let us say, typhoid fever to some domestic guide. It is more than likely that he is unaware of that form of typhoid fever which has constipation as a leading feature. That "the child's death, which was due to an affection of the nervous centres, might have been retarded or prevented by judicious treatment" is a statement such as might indeed be made by an individual who had "a mere smattering of the elements of medicine." But we do not feel competent to adjudicate this case without being in possession of full particulars. There is certainly nothing improbable in the diagnosis of the "ignorant young fellow," so far as the facts which have come to hand are concerned. From what we know of medical men we should, indeed, have thought the practitioner possessed of considerable skill in diagnosis for the reason that, unless the nature of the illness and attendant circumstances were such as to have set the medical man on the scent, we cannot understand why he should have gone, so to speak, out of his way to fill up the certificate. Most practitioners who had doubts of such a case as the one so imperfectly portrayed by "A Country Parson" would have written "convulsions," or some equally equivocal term on the death certificate.

THE CHOLERA.

OUR Paris correspondent writes:—The cholera at Toulon, whatever its nature, is still hovering about that town, though the fresh cases and the deaths are daily decreasing to a notable degree. A few cases occurred at Marseilles, but the malady seems localised at Toulon. The medical men in those towns are now almost unanimous as to the disease being the true Asiatic cholera, and even Drs. Brouardel and Proust, who have just returned from their tour of inspection at Toulon, have, at a meeting of the Superior Council of Hygiene, given it as their opinion that the disease in question is of that type, although of a very benign character. They have founded their opinion on two circumstances—viz., that the disease was imported and that it is distinctly contagious. Dr. Fauvel, however, who is looked upon as the highest authority in France on the subject of cholera, still adheres to the opinion expressed by him from the commencement of the epidemic, that the disease is sporadic cholera. The same opinions were expressed yesterday by the two adverse parties at the Academy of Medicine. A case was reported two days ago in Paris, but on inquiry it turned out to be an attack of simple diarrhœa, from which the patient recovered in twenty-four hours. Three other cases have since been reported, though the report is discredited. The health of Paris is at present stated to be very good. Dr. Koch, of Berlin, is now at Toulon on the same mission that took him to Egypt and subsequently to India.

ANTISEPTIC AGENTS IN SURGERY.

AT the meeting of the Académie des Sciences held on June 23rd, M. Pasteur presented a communication by M. Ratimoff dealing with antiseptic substances. The bacteria chosen for the experiments were principally the pathogenic micro-organisms of charbon and acute septicæmia of animals. In the first series of experiments a number of sterilised flasks plugged with cotton-wool were taken; in some 10 grammes of fresh muscle in divided portions were placed; in others, 10 cc. of ox blood was used; in the last series, a similar quantity of sterilised veal broth was employed. Each flask was treated with two drops of water diluted with earth, and then 10 cc. of the antiseptic solution of different strengths were poured in. All the vessels were then placed in a stove kept at a constant temperature of 33° to 34° C. It was found that the addition of carbolic acid in the strength of 1 in 400 to the veal broth prevented the development of all forms of bacteria, but in order to get the same result with the blood, the strength had to be increased to 1 in 250, and for the muscle-juice to 1 in 160. This difference in strength was still more striking when corrosive sublimate, nitrate of silver, and iodine were employed. The communication of M. Ratimoff is so lengthy, and deals with so many details, that we have here contented ourselves with indicating the principles and method of procedure. We must refer those to whom the technicalities are of special interest to the report in the *Union Médicale* of June 28th.

"SISTER GRACE."

SUCH is the title of a new comedy-drama produced at the Avenue Theatre on the afternoon of the 26th ult., in aid of the funds of the East London Hospital for Children. The author is an active member of the medical profession, and the play itself is stated to be "founded upon incidents of hospital life." This description is, we think, hardly warranted, and, without any disparagement to the author, we are glad to say so; for if such incidents as those introduced into the play were of ordinary occurrence in our general hospitals, the usefulness and good work of these institutions would be most seriously impaired. We sympathise with the author's loyal endeavours to excite public interest in professional work, but must confess that, in our opinion, features of hospital life, terribly dramatic as they are at times, and incidents supposed to occur in the lives of medical men and nurses while employed in attending to and nursing the sick and injured, are singularly unfitted for stage representation. A similar remark applies to the selection of "the accident room" of a hospital as the scene of action in the first two acts. The play, which was well received, was on the whole promising, some of the situations being most effective, and, so far as we know, original. The dialogue contained one or two somewhat cynical remarks on "doctors"; possibly the author considered that a medical play, written by a medical man, and first performed on behalf of a medical charity, might, without some such depreciatory element, appear too professionally obtrusive to the general public. One remark of the hero in reference to a new matron and her attempted "reorganisation" we cordially endorse: "There is not one woman in a thousand fit to manage the affairs of a hospital." Miss Winifred Emery, as the heroine, "Sister Grace," was charming. We may mention that the binaural stethoscope made what was probably its first appearance at any theatre other than that of a hospital. The house was well filled, and we hope a substantial sum will be added to the funds of the East London Hospital for Children.

CISTERNS.

A *Bonâ-fide* Traveller" is indignant because the cisterns of a row of small houses to which his attention has been particularly drawn are not covered, and the water is green. In the interests of health we are, of course, indignant too, but the immensity of the evil somewhat enfeebles our regret. Not only in one row of houses, but in whole districts, this neglect of obvious precaution prevails, and the houses thus neglected are large as well as small. Cisterns in London are, as a rule, either imperfectly protected or so placed as to receive dirt and the foul vapours pervading the neighbourhood. There has been a great outcry for constant service; but, like other demands equally reasonable and urgent, it has been to a large extent disregarded. Now that the cholera scare is upon us, it may be hoped that some of the worst of our remediable nuisances may be removed. A general house-to-house visitation, such as is now being car-

Digitized by Google

ried out in St. Pancras, would result in the unearthing of some strange and startling facts about sanitation. Good sometimes comes out of evil, and when public attention is forcibly, though painfully, directed to long-existing and known, but disregarded, evils, good is done, even though it be evil that does it.

TUBERCLE BACILLUS AND PNEUMONIA MICROCOCCUS.

THE use to which the presence of micro-organisms in the sputa of tubercular and pneumonic patients may be practically put is illustrated by a paper by Dr. J. Samter, of Posen (*Berl. Klin. Woch.*, No. 25, 1884). A debilitated man, sixty-five years of age, suffering from diarrhœa and cough, with scanty expectoration, but without any physical signs beyond those assignable to senile bronchial catarrh, complained one day of great sense of weakness and increased cough. Examination of the sputa by the Ehrlich-Weigert method now revealed, in addition to the bacteria, &c., from the oral cavity, a large number of tubercle bacilli and some diplococci, which resembled those detected by Friedländer in the sputa and inflamed tissues of cases of acute pneumonia. The physical signs continued negative, although the patient became rapidly prostrate, collapsed, and died two days after the detection of the micro-organisms. The necropsy revealed the existence of a walnut-sized cavity at the left apex, and two cheesy foci, with bronchial dilatation; the right lung was in the "first stage of pneumonia," and beset with miliary tubercles; there was also ulceration of the intestines. Here, it was thought, was a case in which there had been an infection by the tubercular and pneumonic virus, the invasion of the pneumonia-micrococcus exciting the tubercular bacilli to greater activity; and it is stated as of etiological interest that a case of typical pneumonia had been admitted into the same ward before the patient in question developed the serious symptoms. Much, however, depends, it appears to us, upon the correctness of the post-mortem diagnosis of the pneumonia in this case; the supervention of acute miliary tuberculosis being *per se* sufficient to induce the hyperæmia, which alone was present. Another case is given where pneumonia complicated phthisis. In this case the sputum contained micrococci but no bacilli, which were, however, found in abundance in a cavity in the lung. Here also miliary tubercle supervened, and the writer evidently is of opinion that infection by the "pneumonia-coccus" is liable to produce a condition favourable to the more rapid growth of the tubercle bacillus in cases where the latter is not making much progress.

THE CASE OF MESSRS. BOWER AND KEATES.

IN the Queen's Bench Division on the 2nd inst., arguments were adduced in favour of a new trial being granted in the action brought against Messrs. Bower and Keates by Mr. Wood, for negligence in not warning him of the danger he was subjecting himself to in sucking a tube which was inserted in his child's throat whilst it was suffering from diphtheria. After consultation, Mr. Justice Field said that the Court came with great regret to the conclusion that the case must be sent to a third trial. The case for the plaintiff was that the medical men should have told him it was diphtheria, so that he might know the risk he incurred, and might, if he incurred it, take precautions to avert the disease, or lessen its severity if contracted. It appeared clearly that no warning of any kind had been given to him. In this case there were several questions to be left to the jury, which he had left to the jury in the case he had tried; but the case at the last trial had not really been put to the jury, and the Lord Chief Justice seemed to have thought the case concluded by the view the jury took, that even if the father had known it was diphtheria he would nevertheless have done the act. It was not a case to be left at large to the jury; it was a peculiar case, and required careful direction to the jury. He regretted that the action should have been brought, no doubt under the influence of mistaken feeling; but he could not, as a judge, be influenced by that view, or against a legal right of action. It was true that one of the medical men had said that a man would naturally wash his mouth in such a case, but then they had said that they would not have let the man do it without warning him. But the plaintiff had no warning at all, and surely there was a case to be put to the jury. It had not, however, been properly put to them, and the verdict was not satisfactory, and therefore the case must go to a new trial.

MICROCOCCUS XANTHOGENICUS.

FRESH experiments made by Messrs. Mozly and Harrison have served to throw discredit on the conclusions of Dr. Freire. Investigations were made with soil taken from the graves of persons who died of yellow fever in the epidemic of 1881, and also with material from the graves of those dead of other diseases, as well as from open fields on which no manure had been used. Previously sterilised chicken soup impregnated with any of these moulds and kept at the ordinary temperature usually became turbid in a few hours, and by the second day assumed a bright-yellow colour, especially on the surface, the colour being most evident in the case of a soil from a yellow fever grave and one from an open field. These appearances were not met with when the soil used had been taken from yellow fever graves where a layer of lime had been placed above the coffin. The coloured liquids, although swarming with bacteria, were injected into guinea-pigs without producing any symptoms as a rule, and certainly none which could be referred to yellow fever. Similar negative results were obtained when decomposing matter was used from the coffin of a person who had died of the disease, the guinea-pigs in such cases apparently dying of simple septicæmia, no bacteria being detected in the blood, the corpuscles of which were considerably disintegrated, and there was no albuminuria. When the "moulds" were cultivated at 98·5° F. the liquid acted much more virulently; but the symptoms were still those of blood-poisoning and not of yellow fever, the absence of micro-organisms in the bodies examined immediately after death being certified.

ANOTHER SPECIAL HOSPITAL.

WE regret to observe that yet another special hospital has been started in London, and that appeals for its support are being circulated at the instance of one of its medical officers among the subscribers to a West-end dispensary to which he is surgeon. It is not, however, of this mode of inviting support that we desire to speak, but of the very specious and misleading character of the circular of this new "Western Hospital for Fistula, Piles, and other Diseases of the Rectum." This document is embellished with the names of a large committee, treasurer, solicitor, architect, and secretary, an honorary consulting physician and two honorary surgeons. We say advisedly that this circular is misleading, as the statement that in the "great metropolitan hospitals but little attention has been given to fistula and piles and other painful diseases of the rectum" declares on its very face. A stronger expression than the one we have used might justly be applied to such a statement as this, which is put forward as the *raison d'être* of this institution. The general hospitals of London are amply sufficient for the purposes for which these "special" institutions are founded, but the former are suffered to languish for want of funds, whilst the public ear is tickled by erroneous statements as to the

Digitized by Google

work of the latter. We have protested before, and we protest again with indignation, against this ever-growing plague of "special hospitals," for which there is absolutely no need, either on the ground of charity or on that of medical science.

EMBOLIC INFARCTION OF MUSCLES.

THAT the muscles, like other organs, are liable to be the seat of embolic infarctions is a subject which is discussed by M. Girandeau in a recent article (*Revue de Médecine*, June, 1884), and he thinks that the rarity of this event is attributable partly to the fact that the muscles are seldom examined post mortem, and partly (probably mainly) to the readiness with which collateral circulation is established in cases of blockage of a muscular artery. It is different in the case of pyæmia, where muscular metastatic abscesses are frequent; but in ordinary cases of cardiac disease, where the viscera show ample evidence of embolism, there are very few records of muscular infarction. Cornil and Ranvier, admitting this rarity, state that they have met with two instances, and that they were characterised by absence of hæmorrhage. Girandeau supplies notes of three cases. The first was a case of chronic mitral disease, with general atheroma. The right sartorius muscle was found to be ruptured, the broken ends embedded in hæmorrhagic effusion, and their muscular fibres granular. The spleen contained two old infarctions. The second case, of long-standing mitral and aortic disease, with arterial atheroma, exhibited a firm, yellow-coloured mass in the substance of the pectoralis major muscle, sharply marked off from the healthy tissue, and resembling a visceral infarct. The spleen, kidneys, and brain were also the seat of embolism. A third case, quoted from Lefevre's thesis (1867), was of the same class, and was further complicated with dry gangrene of the left foot and leg. In this case a yellowish-grey mass of degenerated muscular tissue occurred in the substance of the vastus externus muscle. These three cases were, it will be seen, of chronic heart disease, and Girandeau asks whether these muscular infarctions could not also occur in the course of acute endocarditis in young subjects. *A priori*, such an event is not impossible; but some experiments made by him at Alfort were wholly negative in their result. He concludes that many conditions may be necessary to the production of the event, among which he enumerates degeneration, roughening, and inelasticity of the arteries; an enfeebled heart; and a more or less marked asphyxial condition, impairing the nutrition of the muscle.

THE EDUCATION OF DEAF CHILDREN.

AT the International Health Exhibition, on June 30th, Mr. Dalby, F.R.C.S., read a paper on "The Education of Incurably Deaf Children." He explained the process by which children in early life, who had become incurably deaf through disease, lost the power of speech, by comparing with them the instances where hearing children, having been removed from one country to another, lost their first language whilst acquiring a second; and he selected three classes of cases to illustrate the method which should be employed to prevent dumbness. 1. A child who has entirely lost hearing and can read should be made to read several times during the day, and be taught lip-reading. The constant repetition of the words which it has already used will cause them to be retained by reading, and an increased vocabulary will be acquired by the lip-reading. 2. If a totally deaf child cannot read, it should be at once taught on the pure oral system, and words which it cannot pronounce will by constant repetition be retained. 3. If a child can understand words pronounced in its ear, still better if it can hear a raised voice, it can be taught to articulate new words by making use of the hearing; its articulation whilst becoming deficient can be corrected, and efforts in this direction, added to lip-reading, will enable it to retain speech. Mr. Dalby said it could not be too urgently insisted on that the educational treatment of this character must be commenced immediately after the occurrence of the deafness, or speech would be lost. By processes carried out on the above-mentioned plans, and varied according to the circumstances of the case (of which skilled teachers must be the best judges) great numbers of children may be saved from dumbness.

CRUELTIES TO TORTOISES.

MOST individuals are aware of the difficulties which surround the practice of scientific vivisection, but no such hindrances stand in the way of wholesale slaughter of tortoises for objects quite the reverse of scientific. Your tortoise merchant may import 5000 of his living merchandise in nineteen tightly-closed casks, to the imminent peril of the seething contents, without even the Society for the Prevention of Cruelty to Animals getting scent of the occurrence. The Rev. H. Wilson, Vicar of St. Augustine's, Stepney, has written to the *Standard*, complaining of the insufferable nuisance arising from casks containing full numbers of tortoises in all stages of chemical existence, from the living to the putrefying dead. We are glad that the reverend gentleman has communicated with the medical officer of health, and we think the authorities ought to provide some means of removing, or at least of mitigating, the evil.

DEATH OF DR. MOREAU.

DR. MOREAU, the celebrated alienist, and who was always known by the name of Moreau de Tours, died in Paris on June 26th, in the eighty-first year of his age. He took his degree in 1830, on which occasion he wrote a thesis, "On the Influence of the Physique with reference to the Disorders of the Intellectual Faculties." He had been trained for this specialty at the Charenton Asylum, under the celebrated Esquirol. In 1840 he was appointed physician to the Bicêtre Asylum, and eventually to the Salpétrière, to which he was attached to the day of his death, but latterly only as honorary physician.

NORTH-WEST LONDON HOSPITAL.

IN reference to the resignation of the medical staff of the North-West London Hospital, which we announced last week, and which has excited some comment, we learn that the Committee of Management has deputed four of its members to confer with three representative members of the profession for the purpose of reviewing and, if necessary, altering the rules and arrangements of the hospital, so as to bring them into harmony with those of similar institutions commanding the confidence of the public and the profession.

YELLOW FEVER.

A CORRESPONDENT at La Libertad del Salvador, Central America, in a communication dated May 29th, states that a most fatal form of yellow fever has been raging in that port for some time, where thousands of bags of coffee are stored and are being shipped to England and the continents of Europe and America, but principally to England, and will undoubtedly remain stored there during the hot summer weather.

THE Cavendish Lecture will be delivered by Mr. Timothy Holmes, before the West London Medico-Chirurgical Society, on Friday evening, the 11th inst., at 8 P.M., at the West London Hospital. Mr. Holmes has chosen as his subject the Medical Treatment of the Poor of London.

Digitized by Google

IN the Queen's Bench Division of the High Court of Justice a new trial was on the 30th ult. refused in the case of Johnson *v.* Mudford—the action brought by the coroner for Canterbury and deputy coroner for Kent to recover damages from Mr. Frederick Mudford, proprietor of the *Kentish Observer*, for alleged libel contained in articles which appeared in that newspaper commenting on the plaintiff's conduct at inquests, and which resulted in a verdict for the plaintiff, with damages to the amount of £100.

A PETITION from the Foreign Graduates' Association of Great Britain, signed by Dr. H. J. Hardwicke, president, has been presented to the House of Commons by the Right Hon. A. J. Mundella, in favour of admitting to the Register all foreign degrees obtained after examination and before the passing of the new Medical Bill, by duly registered practitioners; and also protesting against any attempt being made to modify Clause 69, in any sense prejudicial to holders of foreign degrees.

THE epidemic of small-pox which has for some time been prevalent at Liverpool has now attained alarming dimensions. Traffic, except for residents, is in certain streets suspended, and the public institutions for the reception of small-pox patients are full to overflowing. It is stated that the Local Government Board have severely censured the local authorities, and have called upon them to immediately provide suitable hospital accommodation for infectious cases.

SIR WILLIAM HARCOURT stated in the House of Commons on the 26th ult. that he had been informed that the Metropolitan Board intended to appeal against the decision of the magistrates in the case of the Peel-grove Burial Ground, Bethnal-green, by which the bye-laws of the Metropolitan Board of Works were unable to prevent the erection of houses on a burial ground in which 20,000 bodies were buried between 1844 and 1855.

A COMMISSION to inquire into the condition of asylums for the insane and inebriates in Victoria, which has been long called for, has at last been appointed. Curious to state, the commission does not include a single medical man, or, according to the *Australian Medical Journal*, even one member who is known to have any special acquaintance with the matters to be inquired into and reported upon.

THE printing offices of G. Reimer, the well-known medical publisher in the Anhaltische-strasse, Berlin, were seriously damaged by fire on the night of the 24th—25th ult., and the new founts of type introduced this year for special use in the printing of the *Deutsche Med. Wochenschrift* were destroyed.

HIS Excellency the Administrator of Trinidad, has been pleased to appoint E. A. Gaynes Doyle, Esq., M.R.C.S., L.R.C.P. Lond., as Supernumerary Surgeon. The appointment is to date from the 1st instant.

MR. JONATHAN HUTCHINSON'S work on Diseases of the Ear and Eye due to Hereditary Syphilis has been translated into French by P. Hermet and published by Adrian Delahaye, Paris.

WE are asked to state that the hour for the distribution of prizes at St. Thomas's Hospital has been changed from 3 P.M. to 1 P.M. on Wednesday, July 9th.

M. JUNGFLEISH exhibited a specimen of crystallised colchicine at the Académie de Médecine on June 24th.

Pharmacology and Therapeutics.

CHLORIDE OF METHYLENE.

IN a memoir published a few months since Messrs. Regnauld and Villejean gave their reasons, based upon chemical analysis, for believing that the product at that time supplied to surgeons under the name of chloride of methylene was often, if not always, a simple mixture of chloroform and methylic alcohol. Subsequently, with a view of studying the subject physiologically, they prepared what they claim to have been pure chloride of methylene, the action of which was tested on dogs and other animals, comparative experiments being also carried out with chloroform. They report (*Pharmaceutical Journal*) that the results strengthen their previous belief and that the misnamed mixtures owe their properties to chloroform only. The physiological action of chloride of methylene was found to differ entirely from that of chloroform, with the exception that both compounds produce unconsciousness. The symptoms resulting from the inhalation of chloride of methylene were so constant and of such an alarming character that the authors think its employment as an anæsthetic agent during surgical operations is out of the question, and they doubt whether it has ever been so employed. Clonic contractions of muscles of epileptiform and choreiform kind were the alarming symptoms observed, but such movements are by no means confined to one member of the chlorine series of anæsthetics.

MUSK.

Although musk has been long well known in the West, yet, says Dr. Macgowan in his report on the health of Wenchow (Imperial Maritime Customs), it seems worth while to translate what Chinese writers have to say about it. The musk-deer is found throughout the mountains of Yünnan, Szechwan, and Thibet; it is a timid little animal, and often dies of fright. It feeds on juniper leaves and reptiles; snake-bones are found in its stomach. In spring its glandular pouch is greatly swollen and inflamed. The secretion is discharged with the urine. Musk-deer always resort to the same place for micturition, and cover their urine with earth. In such places deposits of a superior quality are found, amounting sometimes to 15 catties (a catty is a Chinese weight of about 1⅓lb.) The article which is most prized is that which falls from the musk-deer on to the ground, and is gathered in grains that are as precious as pearls. These deposits are so pungent that, if carried through a garden or woods, it prevents fructification. The poisonous effect of fresh musk on vegetation is shown also by the blighted appearance of places which the musk-deer selects for its convenience. For some distance around these places there is an absence of plants, and farther off the leaves exhibit a yellow tinge. This valuable substance no sooner leaves the hunter's hands than skilful manipulators adulterate the article for wholesale dealers, who further adulterate it for the trade, by which time it contains only about 10 per cent. of genuine musk. Musk is said to be an anthelmintic, and to cure the bites of venomous serpents.

CHLORAL-QUININE.

A compound of quinine with chloral hydrate has been made by Dr. Mazzara by adding the chloral to an equivalent quantity of quinine dissolved in chloroform. By evaporating the solution and redissolving the residue in ether, the new compound may be obtained in warty crystals, which are said to be volatile at 149° C. and to make fluorescent solutions with acids.

KOUSSINATE OF SODA.

One of the most efficient combinations of koussin is that with soda, which is effected as follows. Any desirable quantity of koussin is dissolved in hot water, to which enough bicarbonate of soda is added to dissolve the koussin entirely; boil this solution with a little animal charcoal for a few seconds and then filter. The solution thus obtained, and which though slightly coloured is clear, is now slowly evaporated in a porcelain dish until dry. The koussinate of soda is an amorphous powder-like mass, of intensely bitter

Digitized by Google

taste and a yellowish-white colour, somewhat hygroscopic, soluble in cold, but more so in hot, water. It is equally soluble in alcohol, excepting the slight excess of carbonate of soda. On account of this great solubility it can be dispensed in all forms, and it is said to have done good service in the treatment of tinea and thread worms.

LOGANIN.

In a preliminary note to the *Pharmaceutical Journal* it has been shown by Messrs. Dunstan and Short that the pulp of the fruit of strychnos nux vomica contains to the extent of 4 or 5 per cent. a new glucoside, which they have named loganin. It has also been shown that loganin is contained in small quantity in the seeds of strychnos nux vomica, and in the pharmaceutical preparations made from them. In the future they hope to investigate the relations of this new body with strychnine and brucine, and also to determine its special physiological action.

ADULTERATION OF CODEINE.

A note in the *Répertoire de Pharmacie* mentions the occurrence of a quantity of tartrate of ammonium (probably the acid tartrate) in a sample of codeine. The tartrate resembled the codeine in its external appearance; it was crystallised in hard rhomboidal prisms, slightly soluble in cold water, but dissolving readily in boiling water, yielding a solution with an acid reaction. The salt is insoluble in alcohol, which property first led to the detection of the admixture and facilitated its separation from the codeine. The want of therapeutical effect which has been observed after the use of codeia might be explained by the presence of adulteration.

ANTIPYRIN.

The introduction of the antipyretic kairin has hardly been twelve months before the world when a new chinolin compound has been described by Knorr of Erlangen, and termed by Filehne "antipyrin" (*Zeitsch. für Klin. Med.*, Band vii., Heft 6). Already records are being published descriptive of the effects of this latest of antipyretic agents. Guttmann of Berlin (*Berl. Klin. Woch.*, No. 20, 1884) gives his experience of it in twenty-seven cases, including pneumonia, typhoid fever, scarlet fever, relapsing fever, facial erysipelas, phthisis, &c. The drug was given in doses of from four to six grammes, generally in two or three portions of two grammes at an hour's interval, in solution or powder; and the general effect was a depression of temperature for at least five hours, often longer. The temperature fell gradually and continuously to the extent of from 1° or 2° Celsius (i.e., from 2·2° to 4·5° F.) or even more, the fall in temperature being accompanied by a fall in pulse rate, and in cases of great depression with profuse sweating. In only one case were any unpleasant symptoms produced, such as vomiting; in all others the drug was well borne. The subsequent rise of temperature was unaccompanied by any rigor, as appears to happen sometimes after kairin. Guttmann observes that quinine in half the dose of antipyrin produces the same effect, but that the cost of the former is much greater than that of the latter. Ranke of Stuttgart (*Deutsch. Med. Woch.*, No. 24, 1884) has prescribed it in thirty-five cases, including pleurisy, pneumonia, typhoid fever, acute rheumatism, tuberculosis, erysipelas, and pericarditis, and confirms the above statements as to its certain and rapid action, with freedom from toxic effects. Injected subcutaneously, antipyrin has a more powerful and rapid influence than when administered by the mouth, a dose of two grammes of a concentrated solution in the former method being equivalent to one of from four to six grammes in the latter. Ranke also thinks it, in general, an excellent substitute for quinine. Lastly, F. May, assistant at the Burgh Hospital of Cologne, gives full details of cases, with charts, &c., in which this drug was employed, in the same journal (Nos. 24, 25, and 26).

KAIRIN.

Some experiments, made by Dr. Quseiralo with kairin in the medical clinic at Genoa, are reported to have shown that when this antipyretic is administered subcutaneously a greater fall of temperature is produced, which commences more rapidly and lasts longer than that following its administration by the mouth, whilst these effects are obtained with smaller and less frequent doses. The hypodermic injection of kairin is said not to produce any general disturbance or local mischief, apart from a slight smarting at the point of puncture, which soon passes away. Injections were used containing from ten to fifty centigrammes of kairin to each gramme of distilled water, brought to a clear solution by the aid of heat, and used while still at a temperature between 30° and 35° C.

ABRUS PRECATORIUS.

M. Patein gives an account of an examination of the external coat of the seeds of jequirity (*Journal de Pharmacie*). A large proportion of carbonate of lime and rather more than the proportion of iron in hæmoglobin has been found in the testa. The colouring matter is soluble in alcohol, and seems to contain a salt of iron. It is precipitated by subacetate of lead as a greenish substance, is turned green by alkalies and reddened again by acids. In a paper read before the Pennsylvania Medical Society (*Pharmaceutical Journal*) Dr. Shoemaker reports the results of some trials with an infusion of jequirity seeds on various affections of the skin. The method was employed on the principle that "granular lids" are cured by the induction of an ophthalmia of croupous nature. Lupoid conditions, epithelioma, and sloughy ulcers were found to be but little influenced by a weak infusion, though when a stronger "emulsio-infusion" was employed a specific inflammation was set up which occasionally, when applied over extensive surfaces on sensitive patients, assumed alarming proportions. The products of the inflammation, however, formed an immense crust, under the protection of which the healing process rapidly went on, leaving a new and healthier ulcer when the scab was removed, so that by repetition of the application cures were speedily effected. Dr. Shoemaker thinks jequirity will prove to be a most powerful agent in certain affections of the skin, though it ought to be used with due caution.

HYDROBROMATE OF CONIA.

Hydrobromate of conia is recommended for epilepsy by Dr. R. N. Wolfenden. The dose given is from a quarter of a grain to a grain and a half, according to age.

VESICARIA GRACILIS.

A new diuretic is mentioned in the *Therapeutic Gazette* for May by Dr. U. S. Newlon of Oswego, who has made some experiments with a cruciferous plant, Vesicaria gracilis, which grows west of the Mississippi, and finds that it is a stimulating diuretic of some power. Its virtues are best extracted by alcohol or acetic acid.

LYTHRUM SALICARIA.

This remedy is highly spoken of by Dr. Campardon (*Bull. Gén. de Thérapeutique*) in cases of acute or chronic inflammations of the gastro-intestinal mucous membrane. Its properties appear to be due to tannin and mucilage. An excessive dose, such as ten to twelve grammes per day, produces gastric disturbance. The application of the powder and infusion has been found of service in the treatment of varicose ulcers. The infusion is made of the strength of thirty parts of the leaves and stalks to 1000 of water. Of the powder the dose is one gramme in a wafer three times a day.

THE INTERNATIONAL HEALTH EXHIBITION.

Group 2.—Dress.

To be healthy a man or woman or child must be properly clothed and fed. This sentence sufficiently indicates the *raison d'être* of the dress department in the present Exhibition. There is much to be said of this portion of the Exhibition. First of all, it is no secret that Mr. Frederick Treves and the Hon. Lewis Wingfield have practically done all the work. Thanks no doubt are due to others, amongst whom we may name General Erskine, Lady Brassey, the Marquis of Lorne, the Indian Government, and that of the United States of America, but the onus of regulating, arranging, and distributing the exhibits has been chiefly on the shoulders of the gentlemen named. The share of the Hon. Lewis Wingfield consisted in the preparations of designs for costumes illustrative of the history of British dress from William I. to George IV. This series of wax figures dressed from contemporary authorities—missals, tombs, statues, and portraits in oil—representing the civil costume of the middle and lower classes from A.D. 1066 to

Digitized by Google

1820, forms one of the most attractive features of the Exhibition. Situated in the West Quadrant, it has frequently been so closely inspected that here, at all events in the evening, free locomotion is not possible. We have also seen the photographers frequently at work on this excellent display. Messrs. Auguste and Co., of Wellington-street, Strand, have executed the costumes; Mr. C. F. Fox, of Russell-street, Covent-garden, have made the wigs; and the wax figures have been done by Mr. Edwards, of Waterloo-road. Reigns during which no important changes in civil costume were made have been omitted. It will be seen that in some instances changes followed each other rapidly, each succeeding reign being marked by a strong individuality (from Elizabeth to Charles II., for example), while in other instances the dress of the lower orders remained much the same for generations. Nearly every case contains a lady and gentleman of the esquire class and also a peasant woman and artisan of the same period. We are informed that this group cost over £1000. From a hygienic point of view it will be seen that many of the costumes and headgears are simply of outrageous characters. Tight-lacing, however, does not, on the whole, seem to have reached so alarming a degree as in the dress of the period. We have not the space for detailed criticism, but those visitors who bear in mind the main hygienic reasons for clothing—viz., to cover the body and maintain all parts at an equable temperature—will have no compunction in condemning most heartily those garments which most loudly call for deprecation.

In cases facing those just commented on there are exhibits of military costume illustrative of the mode in which the British Army was dressed at various periods of its history from the earliest times to the present day, to which are added, for the purpose of comparison, specimens of uniform now worn by the armies of some foreign nations. General Erskine has superintended the arrangements of this exhibit. In an adjacent case the uniform of a hospital sister and hospital nurse, sent by the House Committee of the London Hospital, are shown. Close by these uniforms Messrs. John Richardson and Co., manufacturing chemists, Leicester, have exhibited a complete series of the most inflammable fabrics, rendered entirely and perfectly secure from fire. Here there are different materials largely used for dress purposes, as also examples of ball and evening costumes rendered non-inflammable by chemical processes; these fabrics, it must be confessed, have rather a lacklustre look. Chemically prepared starches and various chemicals, such as tungstate of soda, employed in the manufacture of fire-proof materials, are shown in suitable glass vessels. The action of poisonous dyes in fabrics on the economy remains to be illustrated. Before we proceed with our detailed report of this interesting series of exhibits, we must say something of its general aspect. It is understood that firms and other business men have applied for spaces to exhibit certain processes or articles which bear upon the subject of health. The judgment and allotment of such demands have fallen on the executive of this department, whose head and chief is Mr. Frederick Treves. Now, although much care and pains seem to have been taken to permit only exhibits of decided relation to health, still some exhibitors have been unscrupulous enough to introduce specialities having nothing to do with the subject in question. Visitors will easily pick out the sinners. With regard to the incompleteness of the dress show, it may be said that want of funds is the chief reason for this shortcoming. In some instances, as for example in the making of crape, the application of jute to the manufacture of dress fabrics and the preparation of imitation fabrics, the trades are worked under great secrecy, and so nothing but refusal to exhibit the processes was met with at the hands of those engaged in these manufactures. The manufacture of waterproof fabrics also requires such a high temperature, so much space, and is attended with so much discomfiture, that it had to be left out of the finished exhibition. It was also found impossible to illustrate machine *versus* handweaving. Funds would not permit of the Brussels lace workers coming over, so the lace making is illustrated by operatives from Honiton and Nottingham only. Spinal and thoracic deformities ascribed to tight-lacing, and models to show the position of the viscera displayed by such practices and the like, have not been exhibited. The same must be said of the dress of female operatives engaged among machinery, as also special dresses recommended or in use in factories and occupations of special character, e.g., dresses for lead and other factories, life-saving dresses and firemen's dresses. Dresses of nurses and sisters have been shown, however, as above mentioned. Moreover, in the subject of underclothing the subcommittee suggested that a series of models displaying the first clothing of infants as adopted in the various countries of the world should be shown, but unfortunately this interesting scheme has had to be abandoned. In the Dress Group the number of exhibits is about 120. Here, as elsewhere, we shall only draw attention to articles noteworthy either from their excellence or novelty. In the East Quadrant various sorts of boots and shoes are shown. The exhibits of Messrs. Dowie and Marshall; Messrs. Waterman and Co., Rupert-street, Bristol; Messrs. Lilley and Skinner, Paddington-green; Messrs. Pocock Brothers, 235, Southwark-bridge-road, S.E.; Mr. Henry Bletchley, of Gloucester; Mr. John Wise, 29, Craven-terrace, Lancaster-gate; Mr. Francis Lanagan, 9, Brownlow-street, Bedford-row; and Mr. William Hall, 39, Edgware-road—are all worth inspection, and demonstrate what is wanted in the covering of the feet. An exhibit of a very interesting nature is that known as Barrett's patent, which is an indestructible boot and shoe sole. Into the composition of this sole much of a metallic nature finds its way; the sole is thereby rendered a powerful conducter of heat, and, owing to its unyielding nature, is hardly to be recommended for walking purposes. However, for the poor, with whom boot-leather is such an important item, the attempt to provide indestructible materials must be regarded as one in the right direction. No. 265 is an exhibit of some attraction from the actual presence of Irish peasants knitting jerseys and other articles. This has been done by the aid of Miss Frances FitzGerald, of Valentia Island. A hygienic dress, with divided skirt, is exhibited (No. 271) by Miss Louisa Beck, of 24, Connaught-street, Hyde-park, which, in our opinion, is most becoming. Messrs. Hamilton and Co., 326, Regent-street, exhibit artistic costumes, designed with reference to comfort in wear and adapted to modern requirements; also a divided dress for athletics or ordinary wear, indistinguishable from ordinary skirts. Some excellent things in clothing are exhibited by the Sanitary Woollen System Co. (Dr. Jaeger's). Attention should also be given to the case of the Rational Dress Society (President, Viscountess Harberton), 23, Mortimer-street. The Grey Wool and Spun Silk Underclothing of Mr. William Lewis, 13, Cheapside, seem well adapted to their purposes. Some specimens of silk hose designed for His Majesty George IV. are also to be seen.

In Class XIV. we may notice some exhibits of indiarubber clothing and invalid appliances by George Cording, 125, Regent-street, and also the good gossamer waterproof clothing of the well-known firm of Swan and Edgar. "Warnerising" is a secret process for preparing clothing to resist moths and mildew. Some articles which have been "warnerised" are shown in exhibit, 301. Every description of waterproof garments may be seen in Messrs. Anderson, Abbott, and Anderson's case. Messrs. Ellwood and Sons, of 24, Great Charlotte-street, Blackfriars-road, have on view various forms of head dress made on the air-chamber principle, as recommended for tropical climates; these are good. Worthy of mention is the India gauze underclothing exhibited by Messrs. Thresher and Glenny. Messrs. Howell and James have a good show in the shape of hygienic and hygroscopic dress materials, giving the necessary warmth with the least weight. An interesting and curious exhibit is that of Mr. John Bell's asbestos fireproof dress. The Fleuss diving dress and breathing dress for working in noxious gases are also represented.

The Donegal Industrial Committee have a large exhibit of knitting, spinning, weaving, and embroidery by hand. This is situated in the East Quadrant, and not in the West, as given in the catalogue. The process of glove-making is illustrated in the West Quadrant by Messrs. Dent, Allcroft, and Co. In the Annexe Albert Hall several exhibits are placed worthy of special mention. These are: A model baby dressed in hygienic clothing, shown by Miss Loader; a complete set of underclothing by Misses Benthall, one figure of which, however good from a hygienic point of view, does not strike the eye as a thing of beauty; the Lairitz Pine-wood fabrics; hygienic porous elastic corsets and supporting belts, by Mr. Thomas Steele, of 24, Margaret-street, Regent-street; ladies' elastic anatomical chest expanding corsets, patent abdominal supporters, gestation, nursing, and riding corsets, by Mrs. Ann Wise, of 15, High-street, Manchester-square, W.; crape underclothing, by Mr. Oscar R. Schmitter; combination garments of silk and mixed silk and wool, by Mrs. Bauer, of

Digitized by Google

134, Oxford-street; and last, but not least, Lewis and Allenby's silk long-cloth underclothing, the only possible objection to which seems to be its darkish tint. In the Western Arcade much machinery in motion may be seen, chiefly made up of knitting and sewing machines. The self-acting sewing machine is well worthy of inspection; it takes but two minutes to wind up the clockwork, and this supply of force lasts for one hour; the speed of working can be moderated to any degree desired. A few other matters in this department remain for consideration. The warmth of different sorts of clothing is illustrated by "dummy" thermometers in the West Quadrant. The thermometers indicate the results of experiments made for the Committee by Mr. Whitley Williams. Pure silk and llama wool are seen to be amongst the coolest garments. The heat-absorbing property of various colours and materials is also to be a subject of exhibition. Cloaks made of very hygroscopic material are shown, and the quantity of water which each holds—(*a*) when dry, (*b*) after a little rain, (*c*) when saturated—has been collected and placed in flasks by the side of each cloak. The costumes worn by the Greely expedition, to be lent by the United States Government, do not seem yet to have arrived. In a separate case Mr. Frederick Treves has supplied: (1) plaster cast of normal liver; (2) plaster cast of liver presumably deformed by tight-lacing; (3) plaster casts of normal feet in a child and woman; (4) plaster casts of feet deformed by improperly shaped boots.

PARASITES OF MEAT AND PREPARED FLESH-FOOD.

IN his second lecture at the International Health Exhibition, Dr. Cobbold treated of the cestoid parasites and their larvæ—that is to say, of the tapeworms and bladder-worms, such as hydatids, measles, &c. Meat sent to the markets was liable to contain these entozoa; neither beef, veal, pork, nor even mutton and venison being altogether free. On seven separate occasions he had noticed cysticerci in joints of mutton brought to his own table, and he had described similar parasites from the flesh of a giraffe, as well as from commoner animals. As an argument in favour of hippophagy, it should be stated that horse-flesh was singularly free from parasites of this class, although other tissues, as well as the viscera of equine animals generally, were apt to contain bladder-worms. None of these equine parasites, however, was injurious to man. Having (by means of Sheet No. 3 of the illustrations displayed in the South Gallery) explained the general structure and development of the beef tapeworm, the lecturer dwelt at some length upon the dangers arising from dispersion of ova by the employment of fresh sewage, and upon the inestimable value of experimental research in determining the mode of origin of the different species of tæniæ that attack man and beast. He referred to the labours of Leuckart, Mosler, and various other Continental helminthologists; but he stated that in this particular matter he had conducted more experiments than any one of his foreign co-workers. Reverting to the prevalence of measly beef, it was shown that out of 13,818 beasts slaughtered in the Punjab in the year 1869, as many as 768 animals were infested with cysticerci. This would be at the rate of about 5½ per cent. (5·55). The percentage of the previous year was higher. Passing to the ravages of the pork tapeworm, its comparatively dangerous character was noticed, not a few instances having come under Dr. Cobbold's observation where the cysticerci were lodged in the human brain. Allusion was made to the Mosaic inhibition of swine's flesh, and to the extraordinary prevalence of measly meat throughout the East. In reference to the little tapeworm which proved to be the sexually mature state of ordinary hydatids, he referred to the experimental labours of Von Siebold, Naunyn, Nettleship, and others. Reverting to hydatids, a singular experience was related in connexion with a plate of meat that had been brought to him at a public restaurant. The relative prevalence of the echinococcus veterinorum in England, India, Australia, and Iceland was next referred to, special stress being laid upon the investigations of Dr. J. D. Thomas of Adelaide. As regards India, it was stated on the authority of Dr. James Cleghorn, that of 2109 beasts slaughtered at Mooltan 899 were diseased, and in most cases both the lungs and liver were affected. This was equivalent to 42 per cent. If asked how this was to be accounted for, the reply was that the cattle in India had ready access to tanks containing foul water, and they had frequently been seen to swallow refuse and garbage, in which tapeworm eggs abounded. The ova of the tænia echinococcus, expelled by dogs, must be very thickly dispersed throughout the low grounds of India. As regards preventive measures, Dr. Cobbold insisted upon a more thorough meat-market inspection by competent persons—that is to say, by inspectors who had familiarised themselves with the phenomena of parasitic disease. It was useless to say that officials in general were already well informed on this subject, inasmuch as he had been supplied with abundant proofs to the contrary. During the last thirty years he had received several hundred private communications on the subject of parasites, many of the applicants for information being officers of health. In one instance the cut ends of the intercostal nerves had been mistaken for parasites, and thus meat had been condemned without good cause. In connexion with the temperature necessary to destroy the measles of beef and pork, Dr. Cobbold again emphasised the labours of Professor Perroncito, showing that none of these creatures could survive a heat of 50° C. or 122° F. prolonged for a single minute. At this point of the lecture Mr. Birkbeck, M.P., handed to the chairman a paper requesting information respecting the so-called "mackerel scare," in reply to which it was affirmed that the entozoa of this fish were perfectly innocuous to mankind, whether they were swallowed alive or dead. The parasite most commonly encountered was the Filaria piscium; but there were eleven other internal guests of the mackerel, besides two which fastened themselves on to the gills. Addressing himself in a very pointed manner to those who eschewed flesh food altogether, the lecturer remarked that the vegetarians flattered themselves that by abstention from meat they escaped many of the parasitic ills to which flesh is heir. So they did; but, speaking figuratively, they "jumped out of the frying-pan into the fire." At all events, the most common parasite known in England was almost entirely nourished by the cellulose and protoplasm of vegetables, and it was by means of a vegetable diet, and by the careless use of unfiltered water employed in the washing of salads and other herbs, that certain parasites were introduced into the human frame. Some parasites might be starved by a milk diet, but he feared the same could not be said in favour of an exclusively vegetable diet. Be that as it might, instances had come within his knowledge where the employment of open running waters for domestic purposes had led to local endemic outbreaks of parasitism. He instanced the case of a Yorkshire village, and explained its nature, the passage of entozoal germs from neighbouring piggeries into a little brook being the immediate cause of infection.

At the close of the lecture Sir Lyon Playfair remarked that before he had taken the chair he had been inclined to think that as regards entozoa it was perhaps better to remain in blissful ignorance than to be made acquainted with the disagreeable but highly important facts that had been detailed. He had, however, changed his mind, and now thought that we all owed much to Dr. Cobbold and other workers in this branch of science. It was a pleasure to himself to have presided at a lecture given by an alumnus of the University which he represented in Parliament.

THE NEW WING OF ST. MARY'S HOSPITAL.

ON Wednesday last the Princess Louise (Marchioness of Lorne) opened a new wing which has recently been added to St. Mary's Hospital. Her Royal Highness arrived shortly after three o'clock, when the band of the 18th Middlesex Rifle Volunteers struck up the National Anthem.

Lord Carlingford, K.P., President of the Hospital, received the Royal party, who then proceeded to visit some of the wards. After this the Princess was conducted to a dais

Digitized by Google

erected in the spacious accident ward of the new wing. An address was then presented to her Royal Highness by the President, after which the chaplain offered up prayer, and dedicated the new wing "to the service of Almighty God in the relief of His suffering poor." At the conclusion of the service, which was very impressive, her Royal Highness declared the new wing open, and received a number of purses in aid of the charity.

The Dean of the Medical School then read his report, and presented the students who had been successful in gaining honorary distinction to Her Royal Highness, from whose hands they received their prize certificates.

Dr. MEADOWS, chairman of the Reception Committee, then proposed the thanks of the staff of the hospital and medical school, to which the Marquis of Lorne responded on behalf of the Princess.

As the Royal party passed to the new wing the nurses of the hospital sang a processional hymn. The ceremony was brought to a close by the singing of the National Anthem.

The wards and corridors of the hospital were profusely decorated with flowers and flags, and the whole proceedings passed off with the greatest *éclat*. The approaches of the hospital were densely thronged with spectators, whilst a large and fashionable audience assembled within its walls.

We learn from Mr. Pietro Michelli, the energetic secretary of the institution, that "the building was commenced in June, 1845, the first stone being laid by H.R.H. Prince Albert. It was opened for fifty beds on the 13th June, 1851, and for 150 in June, 1852. On the 23rd May, 1865, H.R.H. the Prince of Wales laid the first stone of a wing to the hospital, which was opened in May, 1867, the hospital being thereby enabled to receive from 180 to 200 in-patients. From 1867 to the present time, or for sixteen years, the accommodation afforded by the hospital has remained the same. Recently, however, another wing to contain seventy beds has been built out of a legacy left to the hospital by the late Mr. J. F. Stanford. The cost of keeping up the new wing will add upwards of £3000 to the yearly expenditure, which the hospital will be unable to meet until further funds are forthcoming."

THE ROYAL BOTANIC GARDEN, GLASGOW.

A MEMORIAL has been addressed to the Lord Advocate by the Senate of the University of Glasgow in relation to the present state of the Royal Botanic Institution of Glasgow, and the interests of the chair of Botany in the university as connected with that institution. After alluding to the position occupied by Glasgow in the medical education of Scotland, and to the importance of botany in the medical curriculum, the memorial states that all authorities agree that the command of a botanic garden, furnished with the proper appliances, is a *sine quâ non* for the right discharge of the duties of the Botanic Chair. The history of the Botanic Garden at Glasgow is as follows:—In the year 1816 a botanic garden was formed in Glasgow by the voluntary contributions of the citizens; and in 1817 the university entered into a contract with the directors of that undertaking, by which, in consideration of a contribution from the university funds to the amount of £2000, certain privileges were secured for the teaching of botany to the students of the university. In the following year, 1818, the Professorship of Botany was founded by the Crown. About the same time a Royal Charter was granted to the proprietors of the garden under the title of the "Royal Botanic Institution of Glasgow;" and shortly afterwards a grant of the same amount as that contributed by the university—viz., £2000—was made by Parliament to the institution. The conditions on which the subscription of the university was given were: (1) That the university "shall have a patrimonial right in the institution, along with the present and future proprietors, to the extent of £2000"; (2) that the said university "shall yearly appoint three of their number to be joint directors of the institution along with the other directors, eight in number . . . in terms of the rules and regulations of the institution"; (3) that "the Professor of Botany shall have the exclusive right of delivering lectures in the public room to be erected in the said Botanic Garden"; and (4) that "the gardener shall . . . supply whatever specimens and plants may be required by the said professor, and shall afford every facility to him during the course of his lectures. These provisions, however, are at this moment, by the serious pecuniary embarrassments into which the Royal Botanic Institution has fallen, threatened with extinction; and an offer made within the last few months on behalf of the Royal Botanic Institution to hand over the whole property to the City Corporation on certain terms, including a stipulation that the corporation should implement the conditions expressed in the contract between the institute and the university as to the privileges to be granted to the university in regard to the teaching of botany, has been declined. The Senate, therefore, having been informed that an application has been made by the Glasgow corporation for the appointment of a Royal Commission to consider the whole subject of the relations of the city corporations to the police burghs, submit the desirability of obtaining the appointment of such a commission, and express the hope that in the event of its being appointed there may be included within its scope the important question relating to the future maintenance of the Royal Botanic Garden of Glasgow, in which the university is so deeply concerned.

WILLS OF MEDICAL MEN.

THE will of Andrew Whyte Barclay, M.D., F.R.C.P., Consulting Physician to St. George's Hospital, formerly of 23a, Bruton-street, Berkeley-square, and late of Whitney Wood, Stevenage, Herts, who died on April 28th last, has been proved by John Barclay, M.D., the brother, Mr. Joseph Noble Beasley, and Mr. John Noble, the executors, the value of the personal estate exceeding £13,800. The testator bequeaths £1000 to his wife, and legacies to nieces and to his executors. The residue of his real and personal estate is to be held upon trust for his wife for life and then for his children or issue as she shall by deed or will appoint.

The Scotch Confirmation under seal of office of the Commissariot of the county of Edinburgh of the trust, disposition, and settlement, dated May 4th, 1877, of William Carmichael, M.D., formerly of the Royal Navy, late of 24, Buckingham-terrace, Edinburgh, who died at Mentone, on Feb. 17th last, granted to Mr. Andrew Thomas Carmichael, the brother and the surviving executor nominate, has just been sealed in London, the value of the personal estate in England and Scotland amounting to over £13,400.

The will of James Smith Ayerst, M.D., late of Stanbury, Lower Warberry-road, Torquay, who died on March 15th last, has been proved by Mrs. Mary Ayerst, the widow and sole executrix, the value of the personal estate exceeding £1900. The testator gives, devises, and bequeaths all his estate both real and personal to his wife absolutely.

The will of John Mure, M.D., Deputy Inspector-General of Hospitals, late of 40, Tedworth-square, who died on May 16th last, has been proved by Mr. Edward Madge Hore and Mr. Frederick Willoughby Ranken Hore, the executors. The testator makes specific bequests to his nephew John Saunders Mure, and to his niece Katherine Mure, and leaves the residue of his property upon trust for his son John.

The following legacies have recently been left to hospitals and other medical charities:—Mr. William John Campbell Allen, of Fannoran, Carrickfergus, £100 to the Royal Hospital, Belfast.—The Earl of Sandwich, of Hinchingbrook, Huntingdonshire, and 46, Grosvenor-square, £1000 each to the Huntingdonshire County Hospital and the Dorset County Hospital.—The Hon. Mrs. Mary Stapleton-Brethertton, of the Hall, Rainhill, Lancashire, and of Lackham, Wilts, £100 to the Royal Infirmary, Brownlow-street, Liverpool.—Mr. John Lancaster, of Bilton Grange, Warwickshire, and Frankfort House, Fitzjohn's-avenue, Hampstead, mining engineer and coal and iron master, £500 to the Royal Albert Edward Infirmary and Dispensary for Wigan.—Major-General Thomas Craufurd Longcroft, of 13, Upper Wimpole-street, the residue of his property, the gross amount of which is over £72,000, to his executor, Mr. Henry Percival Hart, in full confidence that he will carry out the instructions given him, which he intimates are for dispensing comfort and relief to thousands and thousands of his poor and distressed fellow creatures.—Miss Ann Ball, late of 16, St. Paul's-place, Ball's-pond, £200 to the Hospital for Worn-out Mariners in the Merchant Service; £100 each to

Digitized by Google

the dispensary formerly called Aldersgate-street Dispensary which was held in Shaftesbury House, the Ball's-pond Dispensary, the Hospital for Sick Children, Great Ormond-street, the Sea-bathing Infirmary, Margate, the Royal Bethlem Hospital for Lunatics, St. George's Hospital, the Royal Free Hospital, Gray's-inn-road, the Children's Hospital, Shadwell, the Crèche Hospital, Stepney-causeway, the Earlswood Asylum for Idiots, and the Hospital for Children and Adults, Tottenham-green; and £200 capital stock of the East Indian Peninsular Railway Company each to St. Bartholomew's Hospital, Smithfield, St. Thomas's Hospital, Stangate-creek, Guy's Hospital, Southwark, the Metropolitan Hospital, Bishopsgate, the London Hospital, Mile-end, and the German Hospital, Dalston. All the residue and surplus arising from lapsed legacies the testatrix directs her executors to divide between the several hospitals and dispensaries named in her will and codicils.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Sanitary State of Ormskirk Rural District, by Dr. PARSONS. This report was mainly prepared in order to enable the Local Government Board to judge how far the existing arrangements for the discharge of the duties of medical officer of health for the district justified the Board's consent to their continuance. The district is for this purpose cut up into five portions; three of the medical officers of health are Poor-law medical officers, the remaining two do not now hold that office. With one single exception the annual reports of the five officers are stated to have been of a meagre and unsatisfactory character, and, in addition to this, it is evident that some of the officers have, both on account of the demands of private practice and otherwise, not been able to perform their duties either with complete satisfaction to themselves or in such a way as to fulfil the requirements of the orders relating to their offices. Quite apart from the efficiency of the several officers, it seems to us that it is very undesirable that one sanitary authority should have multiple medical advisers as to the sanitary state of their district. Where, as here, the officers are five in number, it is next to impossible for the authority to hold the relation to them that is needed to secure frequent consultation and uniform advice as to matters affecting health; and, though in the matter of pauper sickness there may be some advantage in securing officers who are in constant relation with the poor, yet the advantages to be gained from one single officer who can advise as to the whole of the district, and on whose counsel the authority may at any moment be able to rely, must be regarded as outweighing other considerations. The renewed experience gained by Dr. Parsons as to this rural district goes to confirm this view.

Large Infant Mortality and Prevalence of Fever at Spennymoor, by Dr. PARSONS.—Spennymoor is a colliery town in Durham. It suffers much from overcrowding, for even during a period of commercial depression not a house could be found that was to let; the ordinary death-rate is excessive, and the rates from measles, scarlet fever, enteric and typhus fevers, and diarrhœa are largely in excess of those prevailing in England and Wales generally. The death-rate under one year of age for England is about 14 per cent. of the registered births; in the small town of Spennymoor, with its 5700 inhabitants, the rate reaches 19·6 per cent., and to this high infant mortality, which came under notice during the inquiry, a large portion of the report is devoted. Information being obtained as to the probable causes of this large amount of infant death, the following reasons are assigned for it. The use of artificial food instead of breast-milk; the neglect and exposure of infants by their mothers, who spend much of their time in the public-houses, and who at night time, when their husbands are at work in the pits, relieve their solitude by drinking laudanum or eating opium powder; the consequent abandonment of children to nurse girls, often of eleven and twelve years of age only; and the absence of any proper recreation ground, a circumstance which keeps the children in backyards amidst privies, middens, and offensive drain effluvia. In addition to these evils, it seems evident that the practice of insuring the lives of infants is calculated to become a great temptation to those who are needy by reason of their squanderings, and Dr. Parsons reports that of 58 children under five years of age dying in 1883, in 40 cases the parents received insurance money varying from 15*s.* to £6. Indeed, the children may be actually insured before they are born, and baptism is sufficient to secure the same being paid. One child only three weeks old turned out to be insured in three clubs. Unqualified practitioners attend a large number of the sick, and during four years only ten coroner's inquests were held. This state of affairs is one that in the interests of child life certainly calls for some legislative interference.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Blackpool (Urban).—The death-rate for this borough was 19·5 per 1000 in the estimated population, but deducting the deaths amongst temporary visitors, who were not included in the census returns, the rate is reduced to 16·6. The cases of infectious diseases notified to the sanitary authority included 3 of small-pox, 44 of scarlet fever, 8 of diphtheria, and 23 of enteric fever. The small-pox was prevented from spreading, and the use of the sanatorium materially aided in this. But only 8 of the 44 scarlet fever patients, 2 of the 8 diphtheria patients, and none of the enteric fever patients were isolated in the sanatorium. This experience is so entirely opposed to that obtained in places where proper infectious hospitals have been erected that the authority should take note of it. The present building can only safely receive one disease at a time, and it is hardly to be expected that, under these circumstances, either the medical profession or the public will consent to use it except under pressure of the greatest emergency. There seems to be a want of local spirit as to this matter, as is shown, indeed, by the fact now recorded, that the ambulance available is nothing better than an old dilapidated cab. The authority of this pleasure resort would do well to note what such a place as Bournemouth is doing in this matter. In connexion with the existence of typhoid fever, we observe the need for further action in respect of the safe removal of the excreta of the population. This is especially so as regards the sewer outfall, where the sewage is impounded by the tide, thus occasioning an oscillation to and fro in the main sewers, and so unsealing the traps and driving offensive sewer air into streets and houses. Wherever such defective arrangements are in force, charcoal is placed in the sewer ventilators, and this, which can hardly be regarded as even a palliative, is also carried out in Blackpool. The charcoal apparently goes largely to block the ventilators, and, as elsewhere, it must interfere with the free entrance of fresh air into the sewers. Dr. Welch, whose advice is sound throughout, refers to these "charcoaled ventilating grates" as inadequate to relieve pressure, and advocates a free sewer outfall at all costs.

Northampton (Urban).—This town is now very free from enteric fever; thus, last year only three deaths from this cause occurred amongst a population of nearly 55,000, and in 1880 no such death was recorded. The phthisis mortality is referred to by Mr. Cogan as heavy, and he attributes this largely to the staple trade of shoemaking. This trade is by no means all carried out in well-regulated factories, but mostly at the houses of the working classes, where they toil for many hours in badly ventilated, badly heated, and often damp and overcrowded rooms. In addition, the posture of the body is a very constrained one, and such as to interfere with freedom of respiration. The need for hospital accommodation is referred to in connexion with scarlet fever. We therefore presume that the temporary building which the Corporation possesses is not sufficiently attractive for any but small-pox patients, whose isolation is easier than that of any other cases. A good deal of sanitary work, including the disinfection of houses and infected articles, is in progress. The birth-rate was 35·6, and, with the needed deductions, the death-rate was 16·9 per 1000 living.

THE sum of £235 has been collected by the members of the United Friendly Societies of the north-western district of London for the benefit of the funds of University College and North-West London Hospitals.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5968 births and 3230 deaths were registered during the week ending the 28th ult. The annual death-rate in these towns, which had been equal to 19·8 and 18·7 per 1000 in the two preceding weeks, rose again last week to 19·2. During the thirteen weeks ending last Saturday the death-rate in these towns averaged 20·8 per 1000, against 20·9 and 21·5 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 11·5 both in Brighton and in Norwich, 13·3 in Wolverhampton, and 14·0 in Bristol. The rates in the other towns ranged upwards to 23·0 in Bolton, 23·3 in Sunderland, 23·6 in Blackburn, and 26·1 in Liverpool. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 514, showing an increase upon recent weekly numbers; they included 144 from measles, 122 from whooping-cough, 90 from diarrhœa, 50 from scarlet fever, 42 from "fever" (principally enteric), 39 from small-pox, and 27 from diphtheria. No death from any of these diseases was registered last week either in Brighton or in Norwich, while they caused the highest death-rates in Wolverhampton, Blackburn, and Cardiff. The greatest mortality from measles occurred in Wolverhampton and in Halifax; from whooping-cough in Huddersfield and in Liverpool; from "fever" in Portsmouth and in Cardiff; and from scarlet fever in Cardiff. The 27 deaths from diphtheria in the twenty-eight towns last week included 20 in London, 3 in Portsmouth, and 2 in Cardiff. Small-pox caused 29 deaths in London, exclusive of 20 London cases registered in the metropolitan asylum hospitals situated outside Registration London; also 5 in Liverpool, 2 in Sunderland, and 1 each in Manchester, Sheffield, and Cardiff. The number of small-pox patients in the metropolitan asylum hospitals, situated in and around London, which had increased in the fourteen preceding weeks from 148 to 1316, had declined on Saturday last to 1290; the number of new cases admitted to these hospitals, which had been 155, 332, and 354 in the three previous weeks, declined again to 260 last week. The Highgate Small-pox Hospital contained 83 patients on Saturday last, fewer by 7 than the number in the previous week; 11 new cases were admitted during the week, being but half the number in the previous week. The deaths referred to diseases of the respiratory organs in London, which had declined in the eight preceding weeks from 360 to 227, further fell last week to 218, but exceeded the corrected average by 4. The causes of 81, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Newcastle-upon-Tyne, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Norwich, Nottingham, Salford, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the three preceding weeks had declined from 23·3 to 21·1 per 1000, further declined to 20·6 during the week ending the 28th ult., but exceeded by 1·4 per 1000 the mean rate during the same week in the twenty-eight large English towns. The rates last week in the Scotch towns ranged from 10·1 and 15·6 in Perth and Greenock, to 25·0 in Leith and 26·8 in Paisley. The 590 deaths in the eight towns included 86 which resulted from the principal zymotic diseases, against 88 and 83 in the two preceding weeks; 32 were referred to whooping-cough, 15 to measles, 13 to diarrhœal diseases, 10 to "fever," 8 to scarlet fever, 7 to diphtheria, and 1 to small-pox. The annual death-rate from these diseases averaged 3·6 per 1000 in the eight towns last week, and exceeded by 0·5 the mean rate from the same diseases in the twenty-eight English towns. The 32 fatal cases of whooping-cough showed a decline of 6 from the high number in the previous week, and included 22 in Glasgow and 4 in Edinburgh. The 15 deaths from measles exceeded by 1 the number in the preceding week, 8 occurred in Glasgow and 5 in Dundee. The 13 deaths from diarrhœal diseases slightly exceeded the number in the corresponding week of last year. The fatal cases of "fever," which had declined from 13 to 2 in the five preceding weeks, rose to 10 last week, of which 3 were returned in Glasgow, 3 in Edinburgh, and 2 in Paisley. All the 8 deaths from scarlet fever occurred in Glasgow. The 7 fatal cases of diphtheria were 2 less than in the previous week, and included 3 in Aberdeen and 3 in Glasgow. A death from chicken-pox (classed in Scotland as small-pox) was recorded in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which in the three preceding weeks had been 101, 90, and 74, rose again last week to 85, but were slightly below the number returned in the corresponding week of last year. The causes of 72, or 14·4 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 21·7 and 27·1 per 1000 in the two preceding weeks, further rose to 28·2 in the week ending the 28th ult. During the thirteen weeks ending last Saturday the death-rate in the city averaged 26·5 per 1000, whereas the rate during the same period did not exceed 19·9 in London and 21·6 in Edinburgh. The 190 deaths in Dublin last week showed a further increase of 8 upon the numbers returned in the two previous weeks, and included 14 that were referred to the principal zymotic diseases, against 10 and 15 in the two preceding weeks; 5 resulted from "fever" (typhus, enteric, or simple), 4 from whooping-cough, 3 from diarrhœa or dysentery, 2 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 14 deaths were equal to an annual rate of 2·1 per 1000, the rate from the same diseases being 3·8 in London and 2·3 in Edinburgh. The 5 deaths from "fever" in Dublin last week showed a decline of 2 from the number in the previous week, and the fatal cases of scarlet fever also showed a further decline from recent weekly numbers. The 4 deaths from whooping-cough, however, were more numerous than in any recent week. Three inquest cases were registered, and two deaths resulted from violence; 67 deaths were recorded in public institutions. The deaths of infants had declined, while those of elderly persons showed a considerable increase. The causes of 44, or nearly 22 per cent., of the deaths registered during the week were not certified.

POPULATION ESTIMATES.

The interest that now attaches to the vital and mortal statistics of our large towns invests with considerable importance the method adopted for estimating the population of such towns in the several years of an intercensal period. Population being the necessary basis of all the more important vital statistics, it is essential that due care should be taken to use the most trustworthy methods for the calculation of population estimates. It is evident, however, that very grave misconception still prevails in many quarters as to the method of calculation that should be adopted. Many medical officers of health omit to state in their reports how their estimates of population have been framed, while others have evidently employed false methods. Let us take the report of the medical officer of health for Cardiff in 1883 as a case in point. He states in his report that in framing his estimate he has "adopted the formula used by the Registrar-General, in order that his returns should approximate with that authority." He then proceeds to explain that he has added to the enumerated population of Cardiff in 1881 two and a quarter times the recorded yearly increase of population during the ten years 1871–81. This is incorrectly assumed by the medical officer of health for Cardiff to be the Registrar-General's method. It is true that, failing any more satisfactory basis for such an estimate, the Registrar-General bases his estimate on the hypothesis that the rate of increase of population between the last two census enumerations will be maintained during the current intercensal period. This, however, is very different from assuming that the actual increase will be the same in the current as it was in the last decade, since population increases at a geometrical and not simply at an arithmetical rate of increase. The population of Cardiff increased from 57,363 in 1871 to 82,761 in 1881. The actual increase in the ten years was 24,398, and by Dr. Paine's method the same increase would occur in the present decade; whereas, by the Registrar-General's method, which assumes that the rate of increase, and not the actual increase, will be maintained, the increase of population during this decade will be 36,643, instead of 24,398, as in the last decade. So much for the false method adopted by Dr. Paine under the impression

Digitized by Google

that it was the Registrar-General's method. The result of this method would be to considerably under-estimate the population of Cardiff in each year up to the next census in 1891. Notwithstanding this false method it was somewhat surprising to find that Dr. Paine's estimate for Cardiff in the middle of 1883 was 91,201, and higher by 1168 than the Registrar-General's estimate. This is, however, accounted for by the fact that Dr. Paine gives 85,378 as the estimated population of the borough of Cardiff in 1881, whereas the census report gives only 82,761. In this case the error of facts somewhat balances the falsity of method adopted for the calculation. If both the errors had been in the same direction the result would have caused greater inaccuracy. It is, of course, very desirable that all medical officers of health should clearly apprehend the method adopted by the Registrar-General for framing estimates of population, and we have, therefore, called attention to this instance among many which prove that the official method is very imperfectly understood. This being the case, we are inclined to think that the Census Department of the General Register Office, if such a department exist, should officially calculate all estimates of population required for the purpose of vital and sanitary statistics, in order, as far as possible, to secure uniformity in the method of calculation, and an entirely disinterested consideration of the probabilities of each case. In order to facilitate the calculation of these official estimates, it would be necessary for local sanitary authorities to furnish the Registrar-General with such information as might be judged necessary for securing the probable accuracy of such estimates of population; notably with an annual return of inhabited houses on the rate-book within the sanitary district.

INVESTIGATIONS INTO THE NATURE OF CHOLERA.

To the Editor of THE LANCET.

SIR,—In 1854 I was appointed by the Board of Health of that time a member of a committee for scientific inquiries in relation to the cholera epidemic which broke out in that year in London so suddenly and with such virulence, especially in the Golden-square district. That committee consisted of Mr. Glaisher, F.R.S., Dr. Dundas Thomson, F.R.S., and myself. The reports of that committee were published in due course in a special Blue Book. My portion of the inquiry embraced, amongst other things, the microscopical examination of the blood, urine, and rice-water evacuations of cholera patients. From the appendix to the report on the latter subject, published in 1855, some extracts, in view of more recent investigations, will, I am sure, be read with interest at the present time.

I remain, Sir, yours faithfully,

ARTHUR HILL HASSALL, M.D.Lond.

San Remo, June 15th, 1884.

Extracts from Dr. Hassall's Report on the Microscopical Examination of the Blood and Excretions of Cholera Patients.

"The outward and physical characters of the rice-water evacuations of cholera vary considerably in different samples and in different cases. ..... When submitted to examination with the microscope there are detected in most samples molecules and aggregations of molecules, innumerable mucous corpuscles, single and aggregated, of irregular size and form, and which are frequently imbedded in a mucous base, presenting sometimes a fibrous structure, and molecules and globules of oil. ..... In addition to the above, myriads of vibriones were detected in every drop of every sample of rice-water discharge hitherto subjected to examination. Of these vibriones many formed threads more or less twisted, while others were aggregated into masses, which under the microscope presented a dotted appearance. ..... In none of the samples were sporules or threads of any species of fungus present, or a peculiar body of any kind noticed other than the vibriones mentioned. ..... The presence of vibriones in the rice-water discharge being, so far as my experience goes, constant, it became of importance to determine the circumstances under which they make their appearance, and especially to ascertain whether they were present in the evacuations when first passed. In order to determine this point I made arrangements to obtain specimens as quickly as possible after being voided. I had a microscope ready for use placed in the Abernethy ward of St. Bartholomew's Hospital, London, so that the discharge might be examined immediately that it was passed. In this way I succeeded in examining several samples within two hours of their being voided, and two others from separate cases immediately they were evacuated. In all of these the vibriones were present in large numbers. In one case I examined, in conjunction with Mr. Rainey, some of the rice-water discharge taken direct from the small intestines about twelve hours after death, and in this case also the vibriones equally abounded. In all cases the species was the same. It thus appears that vibriones are constantly present in the rice-water discharge of cholera, and that they are developed in it during life, and while still retained in the small intestines. From observations which have been elsewhere recorded it appears that two of the circumstances necessary to the development of vibriones are a feebly acid, or more usually an alkaline, fluid and organic matter, especially animal, in a state of decomposition more or less advanced. Now, in the rice-water discharge of cholera, both of these conditions are fulfilled. In the first place, it is always offensive, sometimes exceedingly so, resulting from decomposition; and in the second, it is always, so far as my observations extend, highly alkaline. We have next to inquire what is the origin or source of these vibriones, and what their relation to cholera. With respect to the first point, there is no doubt but that there is more than one source for them, setting aside the idea of their spontaneous generation in decomposing organic fluids. It is possible that they may obtain entrance into the stomach and bowels by means of the atmosphere, and it is perfectly certain that they do frequently gain admission through some of the impure waters consumed, in which I have not infrequently detected the presence of vibriones, sometimes in considerable numbers. Once introduced into the alimentary canal, they are brought into relation with conditions highly favourable to their development and propagation, both of which take place with almost inconceivable rapidity; thus they are brought into contact with abundance of organic matter, mostly in a fluid or greatly divided state, and more or less altered by decomposition, and the fluid in which this animal matter is contained is highly alkaline, and its temperature being raised many degrees above that of the external air also promotes greatly the development of the vibriones. Once admitted into the alimentary canal, it is not therefore surprising that they should be developed in inconceivable numbers and with amazing rapidity. I have made two or three examinations of healthy and natural fæcal evacuations at the time of their being passed, and in these I have detected the presence of comparatively a very small number of vibriones. It is most probable that the development of these in such cases takes place in the lower part of the intestinal canal, as it is there that in healthy digestion incipient decomposition first takes place; but further observations on this point, especially in cases of ordinary diarrhœa, are still required. That they should not be present, or if present, only in small numbers, in healthy intestinal evacuations, is satisfactorily explained by the fact that the circumstances favourable to their development do not exist in the same degree as in cholera. The disposition to decomposition does not exist to the same extent, neither are the matters discharged equally alkaline. Without, however, at all supposing that there is any essential or primary connexion between these vibriones and cholera, their occurrence in such vast numbers in the rice-water discharges of that disease is not without interest, and possibly is of importance; thus, their presence seems to indicate that the fluid thrown out into the intestinal canal in cholera, and especially into the small intestines, is in a state more than ordinarily prone to pass into decomposition, and that the fluid itself is more than usually alkaline. A condition of the intestinal discharges more than usually alkaline would assuredly act as a source of irritation to the mucous membrane of the intestines, as alkaline urine does to that of the bladder. The existence of these vibriones in the evacuations may also possibly explain in some degree the success of sulphuric acid in checking the diarrhœa. Thus, that acid when freely administered destroys the con-

Digitized by Google

[redacted] essential to the development of the vibriones and so destroys the vibriones themselves. Thus, it checks the tendency to decomposition, and lessens or neutralises the alkalinity of the fluid poured out by the intestines. The mere presence of such a large amount of decomposing organic matter in the alimentary canal so high up as the small intestines, the principal seat of absorption of the chyle, must exert a seriously depressing influence upon the [redacted]

COLOTOMY AND OSTEOTOMY.

To the Editor of THE LANCET.

[redacted] the introducer of the inguinal operation into this country, and as having performed considerably the largest number of operations, will you permit me in justice a few remarks on colotomy and on another operation, osteotomy, which is just now again occupying the surgical mind.

In your annotation on "Lumbar *v.* Inguinal Colotomy," it appears as if M. Verneuil were the reviver of inguinal colotomy, the fact being that though the operation is in its origin French (Littré's), it has never found favour in France. In Germany the lumbar operation had, till the publication of my cases, entire sway, but since I showed that the intra-peritoneal plan was on every surgical ground the better one, I hear that inguinal colotomy is rapidly gaining ground on the Continent. I have now done fourteen inguinal colotomies, and excluding three on infants with imperforate rectum and one performed on an old patient, and as a last resort, at Dorking, all the cases did perfectly well and lived for some time after the operation. Two recent cases, of course, do not come within the scope of the last clause.

Until the publication of your note I was under the belief that I came fourth or fifth on the list as regards the number of colotomies performed by any surgeon, but, until corrected, it seems that I am second, having now operated on fifty-three cases—thirty-nine lumbar and fourteen inguinal. With the exception of the inguinal colotomies for imperforate rectum (which are always more or less rapidly fatal, and this from the nature of the cases and from delay of early operation), and the Dorking cases, and two of the lumbar cases, all my patients have lived for many months, and in several cases years, after the operation. Fuller details will shortly be published in a clinical lecture which I have recently given at the London Hospital on the subject.

Two cases of Macewen's osteotomy for genu valgum have recently been published in your columns, in one of which the popliteal vessels were divided, and amputation became necessary, and was followed by death. In the other the popliteal artery was divided, and subsequently ligatured with a satisfactory result. Some years ago I pointed out the anatomical dangers of this operation, and recommended diaphysial osteotomy, and now that such grave accidents have occurred [redacted] in the hands of able, skilled, and experienced surgeons—it will, perhaps, be deemed justifiable for one who comes second to Mr. Macewen in the number of osteotomies performed to ask surgeons to adopt the plan which is at once thoroughly efficacious in correcting the deformity, as well as perfectly safe to the patient. In the rarer cases, where the internal condyle is much elongated, I still adhere to my plan of internal condylotomy, but in the large majority of cases I do the femoral (about the junction of the middle and lower thirds) and diaphysial operation. I may add that I never adopt Listerian precautions, and that I have never had a death, whereas several cases have been reported in which, with strict antisepticism, death from some cause or other has occurred.—I am, Sir, yours obediently,

[redacted] W., June, 1884. H. A. REEVES.

[redacted]CE OF KAIRIN ON THE TEMPERATURE IN ENTERIC FEVER.

[redacted]*o the Editor of* THE LANCET.

[redacted] a list of temperatures taken from a patient [redacted] enteric fever, hoping that its publication may be a further inducement to some to try kairin for the [redacted] temperature in some cases of this [redacted]

[redacted] a girl aged fourteen, who had been [redacted] days in the fever before coming into our sanatorium on the 20th of April last. Fresh crops of spots kept coming out for the next twenty-one days, after which they gradually disappeared. The patient was quite unconscious for the first ten days after admission, sometimes comatose and at others wildly delirious. Diarrhœa was throughout a constant and very severe symptom, and was kept in check by creasote and opium; the latter served to relieve the severe pain, referred chiefly to the right iliac fossa, but sometimes diffused over the whole abdomen. There was some hæmorrhage from the bowels about the twentieth day of the fever. The spleen was much enlarged, projecting about three fingers' breadth below the ribs, hard and tender to the touch. The tongue was perfectly dry, brown, and cracked, and there were sordes on the teeth and lips during the whole of the first thirty days in the sanatorium. The urine assumed the dirty brownish-green colour peculiar, I believe, to the exhibition of kairin, while its odour at the same time was fetid; but both these peculiarities disappeared after the drug had been discontinued for two days. The times for taking the temperature were necessarily sometimes irregular, owing to the full state of the institution, and the many duties consequently falling on the matron, to whom this duty was entrusted, and whose accuracy I have myself frequently verified.

I believe that kairin has been the means of saving the girl's life, and shall be glad to see reports of similar cases in which it has been used. At present, however, there seems to be a prejudice against the drug; for having proposed its use to several gentlemen, I have been met by "I am quite satisfied with quinine," or "I don't fancy trying things so much advertised," the latter certainly a curious reason, and one which if consistently followed would prevent one using almost any of the drugs which have been introduced during the last ten years.

* Seven grains and a half of kairin administered.

The temperatures were taken every two or three hours, and the kairin given whenever it was found to be 102° or over. I have omitted many of the observations when below

Digitized by Google

102° for brevity, as they do not affect the evidence of the action of kairin on the temperature. Twenty days only are recorded above, but the next twelve showed temperatures very similar.

I am, Sir, yours faithfully,

Kendal, June 21st, 1884. T. B. GREEN.

"PHYSIOLOGY OF THE FEET."

To the Editor of THE LANCET.

SIR,—While reading with great interest Mr. Ellis's article on the above subject (THE LANCET, June 21st, 1884), I was surprised to find that so careful an observer had fallen into the common error of supposing that, in walking, the toe or anterior part of the foot touches the ground first. The error seems to be widespread, and is taught by some very good physiologists. Text-books on medicine also state that a peculiarity of the gait in locomotor ataxy is that the heel touches the ground first. It is quite true that it does so, because it would be difficult to place the foot otherwise; the peculiarity is in the clumsiness with which it is done. Our plantigrade relatives among the carnivora walk chiefly on the anterior part of the foot, using the heel rather during rest; but the upright attitude of man, with the straight position of the knees, throws the weight largely on the heels in walking. When the foot is put forward the heel is the part nearest the ground, and touches it first; the ball of the toes touches immediately after, and the toes themselves last of all, the action of the foot somewhat resembling that of a rocker. Should anyone have any doubt on the matter, let him watch the passers-by in a public thoroughfare. He will there see walkers, good and bad, of all ages; but they will invariably place the heel first on the ground; a man who did otherwise would be supposed to be practising a burlesque step for the stage. The form of the ankle-joint is suitable to this action, the articular surface of the astragalus being wider in front than behind. Through this arrangement the impact of the heel on the ground, by driving the astragalus forward, slightly separates the articular surfaces, and friction is thus reduced. Here I would make a conjecture as to the origin of raised heels to our boots. Most persons acknowledge the comfort of shoes "with no heels"; and for this reason, presumably, slippers are made without them. Why, then, do we ever wear raised heels? May it not be because the impact of the heel wears out the posterior part of the shoe-leather before the anterior, so that it has been found economical for outdoor walking to have a thick piece over the heel? For the same reason, apparently, the skin over the back of the heel is the thickest on the foot. Of course this does not explain the fancy of women for extremely high heels, which is as unphysiological in its origin as the fancy for "dress-improvers."

I am, Sir, yours faithfully,

F. J. ALLEN, M.A.Cantab.

Royal Southern Hospital, Liverpool, June 28th, 1884.

THE BROMPTON CEMETERY.

To the Editor of THE LANCET.

SIR,—"How long will a man lie i' the earth ere he rot?" is the question asked of the gravedigger by Hamlet, and we all know the facetious reply given. Walking through the Brompton Cemetery, I passed by the grave of one who was for many years the best impersonator of the First Gravedigger upon the English stage, and I thought of the well-remembered scene in the churchyard at Elsinore. There was no earth here, however; but only flint stones, sand, and gravel. In this necropolis thousands of bodies are lying, some of them actually resting upon shelves placed in buildings erected above the ground. The emanations arising from these decomposing bodies poison the air, and the soluble parts, washed out by the rain, must be disseminated under the houses and streets, which are now built close to the burying-place. Day after day processions of hearses and mourning coaches ("a ghastly band") arrive at this cemetery; and the enormity is perpetuated of burying under gravel, sand, and flint stones a mass of human remains in the midst of their living fellows. The gates of this cemetery ought to be closed at once and for ever, and the office at No. 12, Haymarket, appropriated to some less horrible purpose than the one it is now used for.

I am, Sir, your obedient servant,

July 2nd, 1884. JOHN TOPHAM, M.D., F.R.C.P. Lond.

LIVERPOOL.

(From our own Correspondent.)

CITY HOSPITAL FOR INFECTIOUS DISEASES.

AT the monthly meeting of the City Council a letter from the Local Government Board to the Mayor was read. In this it was stated that the Board were clearly of opinion that the Mill-road Workhouse should cease to be used as a small-pox hospital as soon as the City Council made the necessary arrangements for the accommodation of patients. It was resolved to provide temporary hospitals on a site either at the southern or eastern extremity of the borough. It will be remembered that it was stated in THE LANCET some months ago that the use of workhouse hospitals for other than pauper patients could not be justified.

THE CASE OF POISONING YEAST.

At the city sessions, held last week, two men named Gilder, father and son, yeast-dealers, were convicted of maliciously damaging five baskets of yeast belonging to a firm of flour-dealers by poisoning it with carbolic acid. The Recorder, in sentencing the elder prisoner to six months' and the younger to three months' imprisonment, characterised the offence as a very serious one.

THE MEDICAL OFFICER OF HEALTH'S ANNUAL REPORT.

Dr. Stopford Taylor's annual report has just been issued, and contains many interesting details. The total population of Liverpool is estimated at 566,753; the births were 19,207, a decrease of 591; while the deaths were 15,074, an increase of 256 over the previous year. Small-pox is rarely absent, owing to its frequent importation by visitors, emigrants, and others. Scarlatina caused 388 deaths, and measles 618. The deaths of infants below one year amounted to 3686.

THE LIVERPOOL PARISH INFIRMARY.

The parish of Liverpool is one of the largest and most densely populated in the kingdom. Some idea of this is shown in the numbers of inmates in the workhouse and its branches. These are in all 2648, including 1325 sick and infirm. These, again, include 732 persons under medical treatment, 51 being infectious cases.

THE WEATHER.

The weather for the last few weeks has been remarkably fine, and the heat almost tropical in its intensity. It has, however, been tempered to a considerable extent by the sea breezes, of which Liverpool has the benefit, except in unusually calm weather, and so far there have been no cases of sunstroke.

DISCOVERY OF A BODY IN AN EMPTY HOUSE.

While a corporation official was engaged on Tuesday last in an inspection of a house which has been empty for more than a year, he found in a closet in the yard the body of a woman reduced almost to a skeleton. The discovery in the hand of the deceased of a newspaper dated 6th July, 1883, limits the death to within that period. The body was found doubled up, and has not yet been identified. An inquest will be held in due course.

IRELAND.

(From our own Correspondent.)

QUEEN'S COLLEGES COMMISSION.

THE Commissioners, after visiting the three Queen's College, proceeded to hold an inquiry in Dublin, and to receive evidence in respect of various matters bearing on the subjects to be investigated. Among those who gave evidence was the Rev. Dr. Walsh, President of St. Patrick's College, Maynooth, who thought that inconvenience arose from the fact that examiners of the Royal University were professors in colleges, so that students not taught by them did not stand on equal terms with those who were. Dr. Curtis, who had been Professor of Natural Philosophy in Galway College, was of opinion that the matriculation examination fulfilled the purposes for which it was intended; while Mr. Brougham Leech, who was Secretary to a Treasury Commission which

Digitized by Google

inquired into the working of the Queen's Colleges in 1876, said that he was greatly impressed with the high value and excellence of the work done by them. Various medical gentlemen, including Drs. Knight, Macnaughton Jones, Thomson, Roche, and Smith, also gave evidence, and stated generally that opportunities for learning in Cork College were remarkably good, particularly in histology, anatomy, and practical physiology; but hospital practice was not so good as in Dublin, and opportunities of studying morbid anatomy and pathology were defective. The weak point in the Galway College was the clinical material, and the fees for the medical curriculum were too low in the colleges. Several witnesses thought it desirable that a student of the colleges should come to Dublin for his last year. The Commissioners have adjourned their inquiry until further notice.

ROYAL COLLEGE OF SURGEONS.

The vacant Professorship of Surgery will be filled up by the Council of the College on the 24th inst. Although three names have been mentioned as candidates for the post, I am still of opinion that Mr. Edward Hamilton, ex-President of the Council, has the best chance of success.

ADELAIDE HOSPITAL, DUBLIN.

The Hudson Scholarship and Prizes obtained at the recent examinations were conferred last Saturday on the successful competitors. Mr. Bewley, who obtained the scholarships—a gold medal and £30—this year has been awarded in the University of Dublin first class honours, a classical scholarship, first senior moderatorship, first medical scholarship, and other distinctions. He answered 90 per cent. of the questions in ophthalmology, gynæcology, medicine, surgery, and pathology. Mr. Day was awarded the Hudson Prize, consisting of a silver medal and £10; while Mr. Wynne received the medical, and Mr. Healy the surgical prizes respectively. It is to be hoped that next year some better arrangements may be made as regards examining for the surgical prize. One or two days at the furthest, instead of nearly three weeks, ought to afford ample time, and all the candidates ought to be examined together, and, save in the clinical part of it, in the theatre of the hospital openly before the other students.

The Provost and Senior Fellows have awarded the Surgical Travelling Prize, value £100, to Charles R. Kilkelly; and a prize of £25 to Henry J. Bewley.

At the last meeting of the Board of Trinity College, Dr. Charles B. Ball, surgeon to Sir Patrick Dun's Hospital, was appointed an examiner in the place of Mr. R. G. Butcher, who had resigned.

The proposed amalgamation of the Carmichael College with the College of Surgeons Medical School is still talked of, but the difficulties to be overcome appear to me to be insurmountable.

Mr. Keenan, F.R.C.S.I., has been presented with an address accompanied by a purse of sovereigns, on the occasion of his retirement from the post of resident surgeon to Mercer's Hospital, Dublin.

Dr. Cruise has been appointed Physician in Ordinary to the Viceregal household.

Dublin, July 1st, 1884.

LOWER THAMES VALLEY MAIN SEWERAGE SCHEME.

On the 3rd inst., the Select Committee, presided over by Mr. Giles, resumed the hearing of the scheme for dealing with the sewage of the Lower Thames Valley at Mortlake. The Chairman remarked that they did not want any engineering evidence. Mr. Melliss, an engineer, was cross-examined by Mr. Stephens, Q.C., as to the reasons which had induced him to adopt the intermittent treatment instead of the continuous, which latter he had recommended generally as against the intermittent process. Mr. Mellis explained that the engineering exigencies of the site of the proposed works at Mortlake, there being but a small quantity of land, had decided him in favour of intermittent treatment. When asked whether he had any plan giving the details of the scheme, he said that he had nothing but a pencilled plan, and that the whole matter would have to be gone into after the Committee had decided whether the lands ought to be taken. The Chairman did not think it necessary to go into further details of the scheme, for it would not matter to them whether it was the continuous or the intermittent process. The details would be gone into by the Local Government Board.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General William George Nicholas Manley, V.C., is granted retired pay, with the honorary rank of Surgeon-General; Surgeon-Major Robert Alexander Peter Grant is granted retired pay, with the honorary rank of Brigade-Surgeon; Surgeon-Major James Saltus Conyers, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Thomas Kingston, M.D., from half-pay, to be Surgeon-Major, vice H. H. Burford, placed on retired pay.

ADMIRALTY.—Fleet Surgeon Edward Townsend Mortimer has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. Surgeon Henry Beale Collins and Staff-Surgeon Thomas Travers Riordon have each been placed on the retired list of his rank.

The following appointments have been made:—Fleet Surgeon Thomas E. H. Williams, to Chatham Division Royal Marines (for Walmer depôt); Fleet Surgeon Archibald G. Colquhoun, to the *Trincomalee*. Surgeon James O'B. Williams, to Plymouth Division Royal Marines; Surgeon Edward H. Williams, to the *Imogene*.

MEDICAL NOTES IN PARLIAMENT.

The Cholera.

IN the House of Lords on Friday, Lord Carrington stated that it was intended to ask Parliament to renew the Cholera Act which was passed last session, and which expires in September next. The noble lord described the precautions now in force against the importation of cholera, and intimated that it was not intended to send a medical commissioner to Toulon, as the report of the French commissioners would supply the necessary information. Lord Carnarvon expressed his disappointment at the determination of the Government to save expense in so serious a matter.

Over-pressure in Schools.

Earl De la Warr raised a debate on school pressure; and Lord Carlingford, in defence of his department, declared that the new code mitigated the strain on children, and the cry of over-pressure was a huge spectre. He admitted, however, that there was "some small residue of fact" behind it.

The Medical Bill.

As announced in our second edition last week, the Bill was read a second time on Thursday evening, an opportunity for it having unexpectedly arisen through the collapse of the debate on the third reading of the Franchise Bill.

On Monday night, at a late hour, the Committee stage of the Bill was reached, after two divisions, and the consideration of amendments was postponed to Monday next. Amongst those upon the paper is one by Mr. Solator Booth, proposing the appointment of a Pharmacopœia Committee, consisting of six medical practitioners and five pharmaceutical chemists. Several petitions in favour of the Bill have been presented during the week, and five from London against it.

Criminal Lunatics Bill.

On the motion of Mr. Hibbert this Bill was read a second time on Thursday night, and on Friday it was referred to the Grand Committee on Law.

Market Refuse.

On Monday, in the course of an answer as to cholera regulations, Mr. G. Russell assured Lord Claud Hamilton that the Local Government Board would consider the alleged insanitary state of the streets surrounding Covent-garden and other markets in London.

The Small-pox Epidemic.

On Monday, Mr. Russell informed Dr. Cameron that during this year 2628 cases of small-pox had been admitted to the Asylums Board hospitals, and 282 had proved fatal. Outside these hospitals there had been 107 deaths.

On Tuesday, Dr. Cameron called attention to the small-pox epidemic in London, and moved a resolution calling

Digitized by Google

upon the Government to apply to the metropolis "those rational principles of prompt and direct preventive administration, the efficacy of which in circumscribing small-pox epidemics has been demonstrated by the experience of Glasgow and other large towns." In a lengthy and comprehensive speech, the hon. member for Glasgow described the system pursued in Glasgow, which he claimed to be much more successful in securing isolation, notification, and re-vaccination than the fussy and expensive policy of the London authorities.—Dr. Farquharson seconded the motion, and suggested that the Local Government Board should inquire into the causes of these recurring epidemics.—Sir C. Dilke answered the statements of Dr. Cameron in detail, and declined to entertain a change of system while the epidemic was running its course.—After some remarks by Messrs. Anderson and Hopwood, the debate was summarily closed by the House being counted out.

Dr. Crichton Browne's Report.

On Tuesday, Mr. Sydney Buxton obtained an unopposed order for the return of a copy of Dr. Crichton Browne's treatise on "Education and the Nervous System," together with his letter to Mr. Mundella.

On Thursday, Mr. Raikes called attention to the fact that to reprint the treatise was an infringement of Dr. Browne's copyright, and this view being taken by the Speaker, the order was cancelled, on the motion of Mr. Mundella and by the consent of Mr. Buxton.

Volunteer Surgeons.

In reply to Dr. Farquharson, Sir Arthur Hayter said the Secretary of State for War had already under his consideration various schemes for improving the Volunteer Medical Service by instructing the surgeons in field work.

Obituary.

THOMAS BISHOP, M D. ABER., F.R.C.P.L.

THE death of Dr. Thomas Bishop, which took place suddenly and unexpectedly on the 23rd ult., deprives the English medical profession in Paris of one of its leading members. Dr. Bishop received his medical education at the Middlesex Hospital, became a Member of the College of Surgeons in 1842, graduated as Doctor of Medicine at Aberdeen in 1851, and passed the examination for the Membership of the London College of Physicians the same year. He was elected a Fellow of the College in 1871. For many years he practised at Naples, and was physician to the Embassy and British hospital. During the different disturbances and revolutions of which the Neapolitan capital was the theatre, he remained with his wife (a sister of Sir Stafford Northcote) and infant daughter at a post of no little danger, rendering such services as lay in his power. On one occasion, when passing a barricade, he was taken prisoner, and would, without the intervention of an officer, have been summarily shot. Dr. Bishop was a great admirer of art, and whilst residing in Italy he gathered a small but important collection of pictures, sculptures, and antiques, which formed one of the chief ornaments of his Paris residence. For the last twenty years Dr. Bishop had been practising in Paris, his private patients being chiefly amongst the best families. For some years his health had been declining. He suffered from asthma and valvular trouble of the heart, accompanied by a loud musical murmur. He also had an affection of the eyes, of which he was disinclined to talk, which had necessitated an operation that had only been partially successful. These maladies did not, however, interfere with his usual occupations, and in other respects his health was good. Indeed, on the 19th ult. he testified the active interest he felt in the well-being of the profession by giving a dinner at his house to a number of English and American practitioners who form a medical Society of which he was a member. On the 23rd ult. he had risen, as was his habit when unable to sleep, to write and read, and was found dead shortly after in his arm-chair. The loss of Dr. Bishop will be felt deeply by all classes of the English colony in Paris. His personal friends and private patients will deplore the loss of their kind and upright adviser, whilst the poorer members of the community will remember his devotion to them, both as a member of the British Charitable Society and Mission Home, and in countless acts of spontaneous benevolence.

WILLIAM WOOLDRIDGE, M.R.C.S., L.S.A.

MR. WOOLDRIDGE, whose death we announced in our last issue as having occurred at his residence, Withdeane, Brighton, on the 24th ult., was born at Chichester in 1803. He received his medical education at St. Bartholomew's and Aldersgate-street. In 1826 he obtained the licence of the Society of Apothecaries, and in 1827 the diploma of membership of the Royal College of Surgeons. Mr. Wooldridge formerly practised with much success in the Haymarket, but had for some time previous to his death ceased to perform the active duties of his profession. He was a man of spotless integrity, and highly esteemed by all with whom he came in contact.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

Robert H. W. Johnston, John W. Pare, Alfred W. Hughes, Edwin Morton, Edmund Antrobus, Walter M. Eaton and Edwin L. Lees, Edinburgh; Samuel P. Alexander, Glasgow; Charles Whisken, Henry C. Sugden, J. R. S. Park, John P. J. Gornall, Frank C. Andrews, William H. Haslop, J. R. M. Brennan, William Armstrong, and James Elias, Manchester; C. G. May, Cambridge; Reginald E. Johnson, James W. Holmes, and William Dunbar, Sheffield; John P. Cavenagh, Dublin; John Bailey, Edward M. Quinby, C. L. Warke, and Randle Leigh, Liverpool; Frank W. Ramsay, Newcastle-on-Tyne; T. H. Godfrey, St Thomas's Hospital; Cyril G. Hutchinson, W. J. C. B. Pitt, W. H. Date, Birmingham; Julius Coronel, Amsterdam; William Hartford, Dublin; H. H. Sales, Leeds; Charles E. Gooding, Jonathan B. Loring, and George B. Rowell, McGill College, Montreal.

UNIVERSITY OF DURHAM.—At the recent examinations for degrees in Medicine and Surgery the following candidates satisfied the Examiners:—

DOCTOR IN MEDICINE FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Cant, William Edmund, F.R.C.S., L.R.C.P.
Dawson, William Henry, M.R.C.S., L.S.A.
Walford, Edward, M.R.C.S., L.S.A.
Woodcock, John Rostron, F.R.C.S.
Woodman, Samuel, F.R.C.S., L.S.A., L.R.C.P.

Seven candidates entered for this examination.

DOCTOR IN MEDICINE.

Beatley, William Crump, M.B., M.R.C.S., L.S.A.
Vise, Christopher, M.B., M.R.C.S.

Two candidates entered.

MASTER IN SURGERY.

Cock, Frederick William, M.R.C.S.
Hutchinson, Joseph Armstrong, M.B., M.R.C.S.
Jennings, Charles Egerton, F.R.C.S., L.S.A.
Rayner, Hugh, M.R.C.S.
Rowe, Arthur Walton, M.R.C.S.
Salvage, John Valentine, M.R.C.S.

Eight candidates entered.

BACHELOR IN MEDICINE.

Bryan, Frederick, St. Thomas's Hospital.
Caleb, Clement Cornelius, King's College.
*Cock, Frederick William, M.R.C.S., University College.
Dawson, Arthur Willan, Liverpool Royal Infirmary and King's College.
Dixon, Henry William, Durham College of Medicine.
†Edwards, William Rice, M.R.C.S., London Hospital.
Hare, Francis Washington Everard, M.R.C.S., St. Thomas's and St. Mary's Hospitals.
†Hendriks, Cecil Morgan, M.R.C.S., University College.
Jennings, Charles Egerton, F.R.C.S., L.S.A., London Hospital.
†Rayner, Hugh, M.R.C.S., St. Bartholomew's Hospital.
Revely, Joseph Smith, Durham College of Medicine.
*Rowe, Arthur Walton, M.R.C.S., St. Mary's Hospital.
Rumboll, Charles Frederick, M.R.C.S., St. Bartholomew's and Durham College of Medicine.
Salvage, John Valentine, M.R.C.S., Guy's Hospital.

Twenty-six candidates entered.

*First Class Honours. †Second Class Honours.

UNIVERSITY OF DUBLIN.—At the Midsummer session the following degrees were conferred last week:—

BACHELOR IN SURGERY.—Henry Theodore Bewley, William Bullen Day, John Samuel Fenton, Nicholas Charles Ferguson, William Maxwell Hewson, Samuel Hickson, Hugh Nugent Kenny, Robert Morrow, Thomas Parr, George William Powell, William T. Swan, Ludovic Werner, Reginald Joscelyn Windle.

BACHELOR IN MEDICINE.—Henry Theodore Bewley, William Bullen Day, Henry A. Ellis, Samuel John Fenton, Nicholas Charles

Digitized by Google

Ferguson, William Grandy, William Maxwell Hewson, William Lacy Hickey, Samuel Hickson, Hugh Nugent Kenny, Joseph Vincent Manning, Robert Morrow, Daniel R. O'Sullivan, Thomas Parr, George William Powell, William Robert Roper, George Scarr, Henry Shackleton, Telford Smith, W. T. Swan, Ladovic Werner.

DOCTOR IN MEDICINE.—William Thomas Briscoe, James Chute, John Loftus Cuppaidge, Frederick Conway Dwyer, Thomas Carson Fisher, Thomas Charles Moore, Charles Thomas Poland, William Robert Roper, Henry Shackleton.

APOTHECARIES' HALL. — The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on June 26th:—

Beaumont, Edgar, Gipsy-hill.
Hinds, Frank, Gondhurst, Kent.
Lawson, Robert, Nuthank, St. Andrew's, Fife, N.B.
Lewis, Jenkyn, Llanon, Cardiganshire.
Rees, William Thomas, Llanboidy, Carmarthenshire.
Steinthal, Walter Oliver, John-street, Hampstead.

At the recent examination for the prizes in Botany given annually to medical students by the Society of Apothecaries, the successful candidates were adjudged as follows:—

1st.—Ernest Henry Starling, Guy's Hospital. A Gold Medal.
2nd.—Wm. Beecroft Bottomley, St. Mary's Hospital. A Silver Medal and Books.

AT the Worship-street Police-court on the 1st inst., a woman was fined twenty shillings for having wilfully exposed herself in a public place while suffering from small-pox.

A THREE days' fête and fair, for the benefit of the Surgical Appliance Society for the Relief of the Crippled Poor, was opened on the 1st inst., in the Duke of Wellington's Riding School at Knightsbridge.

AT an inquest on the 1st inst. on the body of a boy aged ten years, the jury, in accordance with medical evidence, returned a verdict that death was due to cerebral hæmorrhage accelerated by over-application at the Board School.

IT has been decided to enlarge the Aberdeen Hospital for Sick Children, and ground has been procured for the purpose. The hospital at present contains thirty beds, but when the additions are completed the building will afford accommodation for fifty-four beds, exclusive of an infectious ward, which will contain twelve beds. The estimated cost of the extension is £6700.

CRUELTY TO A FOWL.—On the 1st inst., at Maidstone, a man was fined £5 and costs for inserting a needle into the comb of a cock in order to make the comb stand upright whilst (the bird was being exhibited. The bird had previously taken a prize with a needle in the comb, and the defendant was possessed of a stock of needles for the purpose.

A WANT SUPPLIED.—On the 1st inst, a garden which has been formed out of an old cemetery of St. George's, Bloomsbury, was opened to the public. The ground, which is about two and a half acres in extent, lies at the back of the area occupied by the Foundling Hospital and Brunswick-square, and will be maintained by the authorities of St. Pancras, the cost of laying it out having been defrayed by the Kyrle Society.

FATAL ACCIDENT TO A SURGEON.—The local papers announce the death of Mr. Woods, L.R.C.P.Ed., L.R.C.S.I., of North-lane, near Brough, East Yorkshire. Mr. Woods was thrown from a young horse on Sunday morning, and was found lying on the high road about ten o'clock in an unconscious state. He was conveyed to his residence and attended by Dr. Daley of Hull; but he never rallied, and died on Sunday night.

THE INSTITUTE OF CHEMISTRY.—A petition has been presented to Her Majesty in Council by Mr. William Odling, M.A., F.R.S., and others, praying for the grant of a charter of incorporation, under the title of the Institute of Chemistry of Great Britain and Ireland. The petition has been referred to a Committee of the Privy Council, by whom it will be considered on the 13th inst.

THE CONDITION OF THE POOR IN DURHAM.—The Bishop of Durham presided over a conference of magistrates, religious representatives, medical men, heads of trades unions, &c., on the 28th ult., at Durham, to consider the moral and sanitary welfare of the poor in the county. After addresses had been delivered by the Dean of Durham, Mr. Isaac Lowthian Bell, and other speakers, a sanitary aid committee was formed.

VACCINATION GRANT.—Dr. Hopper of Felling-on-Tyne has received the Government grant for efficient vaccination.

MORLEY HOUSE.—This convalescent home, at St. Margaret's Bay, near Dover, recently established by London working men in connexion with the Hospital Saturday Fund, has received several donations towards a fund of £2000 required for completing the purchase of the freehold house and extensive grounds. Twenty-three beds have been occupied since last July and throughout the winter by London workmen recovering from accident or disease, and three hundred patients have up to the present time received benefit.

SANITARY INSTITUTE OF GREAT BRITAIN.—The anniversary meeting of the institute will be held in the theatre of the Royal Institution, Albemarle-street, on Thursday, July 10th, at 3 P.M. The chair will be taken by the Right Hon. Earl Fortescue. An address will be delivered by H. C. Bartlett, Ph.D., F.C.S., on "Some of the Present Aspects of Practical Sanitation," and the medals and certificates awarded to the successful exhibitors at the Exhibition at Glasgow in 1883 will be presented. The anniversary dinner of the institute is to take place in the evening of the same day at the Holborn Restaurant, under the presidency of Dr. Alfred Carpenter.

THE Cambridge Medical Graduates' Club held its annual dinner on Tuesday, July 1st, at the Marlborough Rooms, under the presidency of Professor Humphry, of Cambridge, who was supported by Dr. Henry Thompson, of St. John's College, Dr. C. J. Hare, of Caius College, Professor Michael Foster, of Trinity College, the Downing Professor of Medicine, and about fifty other medical graduates. The great advance made by Cambridge as a centre for teaching the more scientific branches of medicine was a subject commented on as one for congratulation. During the evening it was mentioned that there are now in Cambridge 300 undergraduates studying medicine.

VICTORIA PARK CHEST HOSPITAL.—In accordance with the custom which has long prevailed at Brompton, the medical staff of the City of London Hospital for Diseases of the Chest a few years ago inaugurated a series of lectures, open to all members of the profession and medical students. On Wednesday week last Dr. Milner Fothergill delivered a lecture on Valvular Disease of the Heart, which was fairly attended. On Wednesday last Dr. Heron lectured on the Treatment of Lung Tubercle. On Tuesday next Dr. Thorowgood will take up the subject of Remedies for Asthma; and Dr. Bedford Fenwick has announced the subject of Cardiac Degeneration from Intra-abdominal Tumours for July 14th.

OVERHEAD WIRES.—On the 1st inst., the case of the Corporation of Bristol *v.* the United Telephone Company was decided. The plaintiffs claimed the right to have control over the erection of telegraph wires within their city, where wires were carried over land which was vested in them in fee; and where wires being carried over streets might be a source of danger to the public. After some discussion, it was admitted that the plaintiffs had absolute right of control where wires passed over their freehold land; and it was agreed that as to any other wire, which was supposed to be a source of danger, that question should be decided out of court. In the end the case was adjourned *sine die*, to allow time for this arrangement to be carried out.

SANITARY CONGRESS AND EXHIBITION, DUBLIN, 1884.—The Sanitary Institute of Great Britain will hold the Annual Sanitary Congress and Exhibition in Dublin this year. The Congress meetings will be held in Trinity College, and the extensive buildings of the Royal Dublin Society at Ball's Bridge have been obtained for the Exhibition. Sir Robt. Rawlinson, C.B., President of the Congress, will deliver the inaugural address on Tuesday, Sept. 30th; and on the same day the Exhibition of Sanitary Appliances will be formally opened to the public. On the second, third, and fourth days of the Congress the meetings of sections will take place, when addresses will be given by the presidents of the sections, and papers will be read, followed by discussions thereon. Prizes, medals, and certificates of merit will be awarded for improved appliances, after being examined by judges appointed by the Council of the Sanitary Institute. The Saturday of the Congress week is reserved for the various excursions which are arranged to take place.

Digitized by Google

AT the annual meeting of the Northern Counties Branch of the British Medical Association, which is to be held this month at Elgin, it is intended to entertain at a jubilee dinner Drs. Cooper, Grigor, and Robb, the first of whom commenced practice fifty-two years ago, and the two latter exactly fifty years since.

TRAINED NURSES' ANNUITY FUND.—The general meeting of the supporters of this fund was held on the 27th ult. The object of the fund is to give a good service pension of £15 per annum to superannuated or broken-down trained nurses who have served three years in a hospital and at least fifteen years as private nurses. Up to the present only eleven annuities have been founded. It was resolved that an annuity costing £400 should be founded to the memory of the late Duke of Albany.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY. The adjourned discussion on Inebriety was opened on Tuesday last by Mr. Jabez Hogg; the president, Dr. Norman Kerr, in the chair; and was continued by Dr. George Harley, Dr. H. Rayner, Dr. C. R. Francis, Dr. Hart Vinen, Surgeon-Major Poole, and Mr. Jas. Stewart. The following were elected honorary members: Dr. Magnus Huss, Sweden; Professor Eugene Carpentier, Brussels; Dr. Binz, Bonn; and M. Magnan, Paris. The following resolution was agreed to: "That this meeting, while recognising in the success so far of the experiment at the Dalrymple Home proof of the value of the Habitual Drunkards Act, regrets its temporary and defective character, and urges the Legislature to pass a permanent measure dispensing with the attendance of the applicant for admission to a retreat before two magistrates, giving magistrates power of committal in certain cases, and enforcing guardians to detain pauper habitual drunkards in workhouses or in homes for inebriates for a time for treatment and cure."

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BECKETT, FRANCIS MEARS, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Workhouse of the Ely Union.

BOURNS, NEWCOME WHITELAW, M.D.Brussels, L.R.C.P.Ed., M.R.C.S., has been appointed Anæsthetist to St. John's Hospital for Diseases of the Skin.

BRUNTON, JOHN, M.A., M.D., has been reappointed, for a further term of four years, Examiner for Pass Degrees in Midwifery and Forensic Medicine, at the Glasgow University.

BUTLER, WILLIAM JOHN, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Castle Donington District of the Shardlow Union, vice Sellow, resigned.

CALLENDER, JAMES, M.B., C.M.Glas., has been appointed Medical Officer for the Parish of Dunscore, Dumfries, vice A. Lorimer, M.D. St. And., deceased.

CARTER, D'ARCY B., L.R.C.P., M.R.C.S., has been appointed Assistant-Surgeon to Sir Titus Salt's Hospital, Shipley.

CASE, F. W. PERKINS, M.B., C.M.Ed., has been appointed Medical Officer for the Fourth District of the Croydon Union.

CLARKSON, JAMES BOOTH, L.R.C.P.Ed., L.R.C.S.Ed. (late Medical Officer British Ship Owners' Company's Service), has been appointed Surgeon-Superintendent, Coolie Service, under the Crown Agents for the Colonies.

COLLINS, WILLIAM JOB, M.D., B.Sc.Lond., F.R.C.S.Eng., has been appointed Assistant Demonstrator of Anatomy at St. Bartholomew's Hospital.

Digitized by Google

DUTTON, WILLIAM HENRY, M.B., C.M.Ed., has been appointed Resident Medical Officer to the Castlemaine Hospital, Victoria.

FREEMAN, G. D., M.R.C.S., has been appointed Assistant House-Surgeon to the Royal Berkshire Hospital, Reading.

GRENSILL, JAMES HEYNES, M.R.C.S., L.S.A.Lond., has been appointed Resident Medical Officer to the Guest Hospital, Dudley, vice Muriel, resigned.

HALPIN, RICHARD F., M.R.C.S., has been appointed House-Physician to the Royal Hospital for Diseases of the Chest, City-road, vice Mr. Waller, whose term of office has expired.

HOLLIS, ELPHINSTONE, M.D., C.M.Ed., has been appointed Medical Officer for the Third District of the Woodbridge Union.

HUGHES, Mr. THOMAS, has been appointed Public Analyst for the Borough of Newport, Monmouthshire.

MCDERMOTT, WILLIAM, M.D.Q.U.I., M.R.C.S., has been appointed Medical Officer for the Sixth District of the Sudbury Union.

MOORE, JOSEPH, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Middlewich District of the Northwich Union, vice Hughes, deceased.

PEARSON, ALFRED W., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Kingswinford District of the Stourbridge Union, vice Parrish, deceased.

RAY, W. J. R., M.R.C.S., L.S.A.Lond., has been appointed Health Officer for the Shire of Seymour, Victoria.

SEATON, EDWARD, M.D.Lond., M.R.C.P., has been appointed Medical Officer of Health for Chelsea, vice Barclay, deceased.

WHITE, W. HENRY, M.R.C.P., has been appointed Pathologist to the Royal Hospital for Diseases of the Chest, City-road, vice Dr. Gabbett, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BURN.—On the 25th ult., at Richmond, Surrey, the wife of Stacey S. Burn, M.A., M.B.Oxon., of a son.

BYLES.—On the 27th ult., at Denton House, Hoolehill, the wife of Henry Byles, M.B.Edin., of a son.

GREATHEAD.—On the 23rd May, at Graham's Town, South Africa, the wife of J. B. Greathead, M.B.Edin., M.R.C.S., of a daughter.

JONES.—On the 1st inst., at Southgate, Eckington, Chesterfield, the wife of G. H. West Jones, M.R.C.S.Eng. & L.S.A.Lond., of a daughter.

LIDDERDALE.—On the 28th ult., at East Hayes, Cheltenham, the wife of Robert Lidderdale, M.D., Deputy Surgeon-General, Bengal, of a son.

MACKINNON.—On the 27th ult., at Millbrook Lawn, Regent's-park, Millbrook, near Southampton, the wife of Brigade-Surgeon C. Mackinnon, Army Medical Department, Retired, of a son.

SMITH.—On the 28th ult., at Fairholme, Twickenham, the wife of Ernest Barrett Smith, M.B., of twin daughters.

SWEETING.—On the 30th ult., at 5, Edith Villas, West Kensington, the wife of R. D. R. Sweeting, Medical Superintendent of the Western Fever and Small-pox Hospital, of a daughter.

WRIGHT.—On the 25th ult., the wife of Dr. C. St. John Wright, Medical Superintendent, St. Mary's, Islington, Infirmary, of a daughter.

MARRIAGES.

BOURKE—BURKE.—On the 1st inst, at the Pro-Cathedral, Kensington, Surgeon Major J. Bourke, Army Medical Department, Woolwich, son of the late John Bourke, C.B., to Angela Mary, eldest daughter of the late John F. Burke, Esq., of Kensington and Clonmel.

DREW—FULLARD.—On the 30th ult., at St. John's, Richmond, by the Vicar, H. Walker Miller, M.A., Joseph Bowerman, L.R.C.P., L.R.C.S., and L.M.Edin., sixth son of the late James Drew, Surgeon, of Stow-on-the-Wold, Gloucestershire, to Florence, younger and only surviving daughter of the late Ed. Fullard, Esq., and step-daughter of the late Wm. N. Symonds, Surgeon, of Priory House, Crowland, Lincolnshire.

GRÜN—BENN.—On the 24th ult., at St. Mary's Church, Putney, by the Rev. Sir John Molyneux, Bart., cousin to the bride, assisted by the Rev. J. Lowndes, M.A., Edward Ferdinand Grün, M.R.C.S., of Putney, to Sidney Veriana Benn, eldest daughter of Edward Chawner, Esq., late Captain 77th Regiment, of Newton Valence, Hants, widow of the late St. John Benn, Esq.

HARGRAVE—MACLEOD.—On the 24th ult., at St. Mary's Parish Church, West Derby, Liverpool, by the Rev. Canon Stewart, John William, son of John Hargrave, of St. Ann's Lodge, Burley, Leeds, to Constance Helen, youngest daughter of the late William Macleod, M.D., of Ben Rhydding, Yorkshire.

MCALDOWIE—BIRD.—On the 2nd inst., at Stoke-on-Trent Parish Church, by the Ven. Sir Lovelace T. Stamer, Bart., Archdeacon of Stoke-on-Trent, Alexander M. McAldowie, M.D., to Katie, only child of Thomas W. Bird, of Boothenwood.

SIMMONS—HICKS.—On the 25th ult., at Holy Trinity Church, Wallington, E. Walpole Simmons, M.B., M.R.C.S., L.S.A.Lond., of Fairbridge House, Upper Holloway, to Amy Louisa Ida, daughter of R. Hicks, Esq., of Wallington, Surrey.

TULLOCH—CUTHBERT.—On the 4th ult., at St. Andrew's, Tobago, West Indies, by the Rev. Dr. Engledow, John Patrick Tulloch, M.A., M.B., C.M.Edin., to Isabella Emily, elder daughter of the late Robt. Cuthbert, of Dublin.

DEATHS.

PARSONS.—On the 30th ult., at Meadow Dowlish, Arthur Daniell Parsons, L.R.C.P. and M.R.C.S., aged 26.

WOODS.—On the 29th ult., at Brough, East Yorkshire, John Woods, L.R.C.P.Ed., L.R.C.S.I.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, July 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M., each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M., each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

Tuesday, July 8.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, July 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Annual General Meeting.

Thursday, July 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, July 11.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

Saturday, July 12.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EDUCATIONAL MUSEUMS.

MR. THOMAS LAURIE, of Paternoster-row, has issued in pamphlet form some "suggestions for establishing cheap popular and educational museums of scientific and art collections, and industrial productions and inventions, in all towns, villages, and districts; also for their classification, arrangement, and exposition on a new plan, making them available for pupils in lower and middle-class schools and colleges, mechanics' institutes, science and art classes, and for the instruction and recreation of the general public." Mr. Laurie considers the present time favourable for the establishment of such museums, which the peasant, artisan, and youth could frequently visit, to obtain practical information suited to their respective requirements, as well as refreshment of mind.

H. H. is referred to a general notice at the head of this column.

Mr. J. R. Lunn.—THE LANCET, March 1st, 1884.

"BURIED ALIVE."

To the Editor of THE LANCET.

SIR,—Canon Williams's letter has given rise to so much correspondence, and a great part of it so wide of the mark, that I may be pardoned for supplying you with further details, as one of the medical men at Llanelly, and one to whom the family of the poor woman is well known.

In the first place, I have to find fault with Canon Williams's letter. He described the condition of the remains as if he had seen them, thus lending to the description the weight of his authority, whereas the anomaly was seen by the sexton only, who described it to the Canon. I have no desire to impugn the sexton's veracity, though his statement is not so weighty as the Canon's. The deceased, aged seventy-three, died on Easter Monday, 1873, at 8 A.M., and was buried about mid-day the following Friday. She had been suffering from very extensive varicose ulcers for twenty years, was asthmatic, and died dropsical. For a long time before her death she had been unable to move without help. The body was placed in a strong, well-made, oak coffin. On the Thursday night before the burial there was frothy mucus oozing from the mouth and nostrils, and the body was so swollen that the coffin lid had to be forced to enable its being secured by screws. These facts I have from two sons-in-law (one of whom is a carpenter) and a daughter, all of whom witnessed what I have described, and they are, I think, sufficient to destroy the notion of a live burial; and it had been well had our vicar taken counsel and inquired carefully into these matters before rushing into print and giving rise to such false and disquieting alarms. Again, the soil in that part of the country in which the deceased was buried is exceedingly wet at certain seasons of the year. New graves in wet seasons occasionally have to be bailed out to effect decent burial, and it is probable that bricked graves may become so filled with water as to float the coffins.

Assuming the description given by the Canon to be correct (and for reasons stated I think it should be taken with caution), have we not factors adequate to account for the anomalous position of the remains without attributing it to live burial? I think decidedly yes. The well-seasoned wood of the coffin becomes swollen by the moisture within and around, and is thus almost "hermetically sealed." Decomposition proceeds within, gas is generated to any extent, the coffin may be afloat, and tension within increased until (probably at the stage of colliquative degeneration) the lid is burst open and the remains thrown into the position they were stated to be found in. An old sexton tells me he has found three or four bodies presenting similar appearances after being buried for a number of years. The idea of an old woman of seventy-three, who died (*sic*) in a state of extreme asthenia, after giving no evidence of life for over four days, suddenly waking up and bursting open a strong oak coffin lid firmly secured by four screws, seems to me the height of absurdity.

I am, Sir, yours truly,

June 26th, 1884. [illegible] WILLIAMS.

A TAILED CHILD.

WE extract the following paragraph from *Nature*:—"Mr. H. W. Eaton of Louisville, Kentucky, writes to *Science* that the *Commercial* of that city for May 17th and 18th gave accounts of a tailed child recently born there. As such cases are of scientific interest, and are very rare, a party of four, including a prominent doctor and Mr. Eaton, concluded to investigate the case:—'We found a female negro child, eight weeks old, normally formed in all respects, except that slightly to the left of the median line, and about an inch above the lower end of the spinal column, is a fleshy pedunculated protuberance about two and a half inches long. At the base it measures an inch and a quarter in circumference. A quarter of an inch from the base it is somewhat larger, and from that it tapers gradually to a small blunt point. It closely resembles a pig's tail in shape, but shows no sign of bone or cartilage. There seems to be a slight mole-like protuberance at the point of attachment. The appendage has grown in length about a quarter of an inch since the birth of the child. The mother, Lucy Clark, is a quadroon, seventeen years old, and the father a negro of twenty, both normally formed.' In Darwin's 'Descent of Man,' vol. i., p. 28, he speaks of a similar case, and refers to an article in the *Revue des Cours Scientifiques*, 1867–68, p. 625. A more complete article is that by Dr. Max Bartels, in *Archiv für Anthropologie* for 1880. He describes twenty-one cases of persons born with tails, most of them being fleshy protuberances like the one just described."

An American Graduate.—Such advertisements would be regarded in the mother country as disgraceful; but medical ethics in the colonies can, perhaps, hardly be judged by the same standard as that acknowledged at home.

Anxious Inquirer should consult his medical adviser.

Dr. H. B. Trytton.—Very soon.

SCARLATINAL URÆMIA.

To the Editor of THE LANCET.

SIR,—In cases of uræmic poisoning following scarlatina we are assured that pilocarpine, brisk purgatives, hot baths, and the application of leeches are potent remedies, while bloodletting is lauded by many as preferable to them all in urgent cases. As illustrating the beneficial effects of the latter mode of treatment, I desire a portion of your valuable space to record some particulars regarding a case recently under my care, and that they may stand as a contrast to the line of treatment recommended by a correspondent in your issue of Feb. 9th, 1884—the latest communication to THE LANCET on this subject. In his letter of that date Dr. Wm. V. Lyle expresses the opinion that appropriate general treatment, with the local application of leeches, were the means absolutely necessary in most cases. My patient, a boy twelve years of age, after suffering from scarlatina, became dropsical. The swelling of the face was thought to be the result of toothache, and little attention was paid to it, so that, as sometimes happens, professional aid was not asked until convulsions had set in. I at once ordered a dozen leeches to the head, bitartrate of potash as a purge, and sinapisms over the kidneys. Only two of the leech-bites continued to bleed copiously, and notwithstanding free purgation and profuse sweating, I could notice no improvement. So violent were the convulsions that the parents, witnessing one of them, supposed the child *in articulo mortis*, and requested me to let him alone. I allowed twenty ounces of blood to flow from the elbow, thus relieving the much congested head and chest, and putting a stop to the alarming symptoms. The general treatment was meanwhile persevered with; but within twenty-four hours the dreaded convulsions recommenced. I at once undid the bandage, and took away five ounces more blood, with marked advantage to the little fellow. One would have imagined that morphia and bromide of potassium would now prove adequate aids for the successful completion of the case; but all my efforts seemed for a moment doomed to end in failure. A careful note of all the symptoms, which were chiefly great difficulty of breathing without any inflammatory mischief in the chest—very different, indeed, from the panting respiration consequent upon loss of blood—laboured action of the heart, dilated pupils, with a degree of coma and slight convulsions, forced upon me the conviction that a further loss of blood would do good, and accordingly I bled afresh to six ounces. Thus, altogether, in three days, I took away thirty-one ounces of blood. The urine was loaded with albumen, and, although this fact indicated a condition of kidney forbidding the use of cantharides, I was compelled to fly-blister the occiput for the relief of basilar trouble, doubtless of uræmic origin. Iron and quinine mixture in the course of a day caused the albumen to all but disappear, while the blister cleared up the head symptoms, and my patient was convalescent on the fifth day of my attendance.

I am, Sir, yours truly,

June 13th, 1884. R. McK.

An Old Subscriber.—1. We do not think lunatics enjoy any immunity from ordinary disease, except such as may be incompatible with, or unlikely to occur to them in, their special mode of life.—2 and 3. The proper way to put the facts would be that scientific research tends to show that the so-called senses are only modified or specialised manifestations of the faculty or power of receiving impressions from external objects by direct physical influence.—4. We believe not.

Mr. H. St. G. Stewart.—It is very much a matter of opinion.

Digitized by Google

THE LALANDE BATTERY.

THE Lalande battery is said to yield residual products of more value than that of the original materials used—in fact, the electric current may be regarded as a kind of bye-product. It is evident, however, that the introduction of this battery to any considerable extent for electric purposes would tend to lower the value of the residual products. The battery is composed of a series of cells, each consisting of an iron tray containing oxide of copper, over, but not in contact with, which is a zinc plate; the remainder of the tray is filled with a solution of caustic soda. When the battery is in action, oxide of zinc and metallic copper are produced. The oxide of zinc can be recovered from the solution of soda, and is estimated to be worth 25 per cent. more than the metallic zinc.

Mr. Albert E. Hamilton.—"Brown bread" is too indefinite a term to admit of replies being made to the questions asked.

Mr. Thomas P. Smith, M.B.—Centralblatt für Klinische Medizin, vol. II., 1882.

THE BROMIDES.

To the Editor of THE LANCET.

SIR,—About two years ago I suffered from intense headache, having a sensation as if my head were ready to burst, which was accompanied by noises in the ears. I put myself under a course of bromide of potassium, but finding little or no improvement, I resorted to my friend Dr. Oscar Jennings for advice. Dr. Jennings finding me rather depressed, which condition he thought was attributable to the prolonged use of the above salt, prescribed the following mixture:—Bromide of potassium four drachms, bromide of sodium two drachms, bromide of ammonia two drachms, distilled water twelve ounces; a tablespoonful of this solution was to be taken every two, three, or four hours, according to the urgency of the symptoms. After the first day I felt considerable relief, and after having taken the mixture for about a week I went back to Dr. Jennings, who, finding a feeble action of the heart, recommended me to take five drops of the tincture of digitalis with each dose every four hours. In another week I was completely cured of my headache, which, however, left me rather weak. He then put me under a course of chloride of gold and sodium, which entirely set me up, and I have since had no return of the symptoms. I must also mention that as an amazed eruption broke out on my body, Dr. Jennings prescribed the addition of five drops of Fowler's solution to each dose of the mixture, which I was to take only morning and evening. I have related this case as a hint to your correspondent "Bromide," whose letter was published in THE LANCET of last week. I have since tried the above treatment with my patients in similar circumstances, and always with the best results. I may also mention for his information that the method adopted by Professor Charcot in the treatment of epilepsy is the administration of the three bromides in much the same doses as given above, which he goes on increasing for three or four weeks, then coming back to the original dose and continuing the mixture as before for an indefinite period. By this method Professor Charcot proposes to prevent the accumulation of the salts in the system.

With respect to disguising the briny flavour of the bromide salts, I would recommend your correspondent to mix them with the syrup of glycyrrhiza, as is proposed by M. Gérard Leguë, a pharmacien, by which their acrid taste is completely covered.

I am, Sir, yours obediently,

Paris, June 24th, 1884. ALEX. BOGGS, M.D.

Dr. K Kirk (Partick).—The paper would be acceptable. Engraved blocks only can be used by the printer. Bourdeville's cases were published in the *Progrès Médical* for 1880, p. 709.

Mr. R. de Tomasini's letter arrived too late for notice this week.

RABIES CANINA.

To the Editor of THE LANCET.

SIR,—In sequence to your just observations on the annoyance caused by the barking and howling of dogs (in the last issue of THE LANCET), allow me to make some remarks on the creation of rabies in dogs. You must justly assert that it is neglect and misery which are the origin of the cries which make "night hideous." Such, also, is the fact relative to canine madness. Neglect, misery, unwholesome food, unnatural confinement, are often the root from which that dire disease springs. When a mad dog bites many people he sometimes quits scores for a long series of brutalities, insults, and oppression inflicted upon him by the [illegible] more ignorant portion of the human race. The hard blow, the [illegible], the loud curse, the vile annoyance, the insulting word, the [illegible], the carrion food, the shortened chain, the rotten straw, the dirty kennel (appropriate name!), the bitter winter's night, the [illegible] of summer, the dull and dreary years of hopeless imprisonment—ultimate there; and the cup man has poisoned man is forced to drink. In addition to the above, the confining of dogs, and thereby preventing them from having access to their natural medicine, and also their natural intercourse, is certainly calculated to seriously derange their health. Professor David Low, F.R.S.E., in his able work on "The Domesticated Animals of the British Isles," makes some sagacious observations on unnatural and ignorant treatment of the canine race.

[illegible] of preventing rabies by tying together the jaws of dogs, or by [illegible] or incarcerating the animals, is as senseless as issuing a "bull" against a comet. I am, Sir, your obedient servant,

Macclesfield, Cheshire, July 1st, 1881. GEORGE R. JESSE.

VIVISECTION.

AT the annual meeting of the Pennsylvania State Medical Society, recently held at Philadelphia under the presidency of Dr. Henry H. Smith, a report upon a communication from the Anti-vivisection Association was read by Dr. Weir Mitchell, chairman of the committee appointed to consider the subject. The attempts to control vivisection by law were deprecated, in view of the restrictive effect of the licensing system in force in England. Dr. Mitchell is about to institute experiments on snake-poison which cannot be carried out in England on account of the law. The Society passed the following resolution, recommended by the committee:—"That in view of the attempts which have been, or are to be, made to obstruct by restrictive legislation the progress of experimental medicine, this Society desires to express its earnest conviction that experimentation on animals is a most useful source of knowledge in medical sciences; that it is the means by which many important discoveries, both practical and scientific, have been accomplished; that its direction and supervision can be properly entrusted only to members of the medical profession; and that its restriction or prohibition by law would inevitably retard the acquisition of knowledge in respect to healthy and morbid actions, the cause and prevention of disease, and the improvement of the medical art." On motion, the report was accepted, the resolution adopted, and the committee continued.

"SHOULD ENTERIC FEVER CASES BE ISOLATED?"

To the Editor of THE LANCET.

SIR,—I shall be glad if you can find space to allow me to give the history of a case, or rather series of cases, of enteric fever bearing strongly on the information required by "Dilemma" in your issue of the 28th ult. A lady living in the vicinity of East India-road contracted typhoid fever, complicated towards the last with severe diarrhœa, and from which at about the end of three weeks she succumbed. During the latter part of her illness her sister, a patient of mine, living in Dalston, had been in almost constant attendance upon her, in addition to the regular nurse. On her return home, and a few days after her sister's decease, I was sent for, and found her suffering from fever, which soon proved to be enteric, and gradually became very aggravated, and she also died of exhaustion from the severe purging, which increased towards the last. On this patient another sister, a married lady residing in Islington, was most assiduous in her daily attentions. She also sickened soon after returning home, and succumbed to the disease. These three ladies were each attended by their respective medical advisers. The late Dr. Tanner, who was intimately acquainted with them all, saw the three cases almost daily throughout the greater part of their illness, and in my case showed great interest. In recommending his favourite remedy for exhaustion—the cold infusion of beef with brandy—he expressed to me that he only wished he could be the nurse as well as the physician, so anxious was he to save the life of this, the second, patient.

Although I have seen a good deal of typhoid fever, these are the only cases I have ever seen assuming a contagious form. Every precaution was taken to disinfect the secretions in my own and the preceding case, and no doubt in the third. Neither the nurses nor domestics who were brought most in contact with the secretions seem to have suffered. The sisters were most affectionate towards one another, and when ill they tended each other, and thus were brought in contact with the patient's breath, the exhalation of which towards the last, although exceptional, may have undergone some change, and so become infectious.

I have not seen Dr. Tanner's last work; it was not then compiled. I should think he must have alluded to these three cases, which, I think, are somewhat unique in their history, and I have no doubt he must have left full notes in reference to them.

I am, Sir, yours truly,

Kingston-on-Thames, June 30th, 1884. GEORGE MUNDIE.

Perplexed.—It would be correct to put "Physician and Accoucheur" after the name. The word "Surgery" must be regarded as technical.

RUPTURE OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—I have read with interest the case of rupture of the uterus narrated by Mr. J. McKenzie Booth in THE LANCET of June 21st. But in remarking on the case Mr. Booth seems to me to have lost sight of one important element in the cause of the rupture. Though amongst the most frequent causes of rupture of the uterus, as given by Traak, is mentioned ergot, Mr. Booth appears to lay no stress on the action of this drug. Now, when one considers that ergot induces powerful and continuous contractions of the uterus, one can hardly see the benefit to be derived from administering the drug towards the end of the first stage of labour, more especially in a case where the operation of turning has to be undertaken afterwards. In the second stage of labour doubtless ergot is sometimes beneficial, but here we have a safer and more effective agent in the forceps. In the third stage of labour I have been struck with the much greater ease with which the placenta can be expressed when no ergot is given. And when we have to deal with a case of adherent placenta the ergot can only prove an obstacle to the operation of peeling off the placenta. The routine practice of giving ergot in every case of labour, as recommended by some authorities, seems to me an unscientific proceeding.

I am, Sir, yours truly,

Scalloway, N.B., June 27th, 1884. A. WATTIE, M.B. Edin.

"HOUSING OF THE POOR IN NEW YORK."

In our annotation last week on the above subject the name given as "D. Willis" should have been D. Willis James. We understand that Mr. James Gallatin, president of the New York Sanitary Reform Society, spent a great part of two winters at Albany to secure the legislation referred to, and his name also should have been mentioned in connexion with the matter.

WASHING OUT THE BLADDER.

To the Editor of THE LANCET.

SIR,—*A propos* of Sir Henry Thompson's lecture on the desirability of making a perineal opening and washing out the bladder through a tube, which must be retained for some time, a practical difficulty occurs, and is of considerable inconvenience, in the tube, however carefully tied in, often slipping out, owing to the restlessness of the patient, and sometimes to the fact that he pulls it out himself. A catheter is too rigid; the tube must be soft and pliable, and only just kept in the bladder, and to retain it in that position is no easy matter. In a case at present under treatment I found the tube out several times during the day, and the patient suffering much discomfort from the consequent wetting of the bed and the irritation caused by the reintroduction of the tube. To obviate this, I passed the piece of tubing, a large-sized drainage-tube with bevelled end, through the hole in the little shield supplied with the ordinary Higginson's syringe, passed a safety-pin through the tube, and secured with a thin strip of plaster to the shield. A piece of protective silk was placed over the wound, a hole being cut in the centre for the tube, and the shield kept in position by tapes passed through holes at the ends, and fastened to an abdominal bandage in the usual way. By this simple contrivance the tube is kept accurately in position, and the urine passes only through it, instead of dribbling past it into the bed. The other end is carried into a convenient vessel, and the washing-out process is easily performed. Attention to such little matters of detail seems greatly to influence the success of an operation.—I am, Sir, yours truly,

J. G. MARSHALL, M.B.Cantab., M.R.C.S.,
June 24th, 1884. House-Surgeon, Doncaster General Infirmary.

Mr. F. Berry.—Probably there is some truth in the assumption that the individuals comprised in a triple birth have, *ceteris paribus*, less than the average amount of vitality.

DENTAL REGISTRATION.

To the Editor of THE LANCET.

SIR,—Will you allow me to explain to your correspondent who was answered on page 1183 of THE LANCET for June 28th that dentists can now only be registered after having passed the same preliminary examination in Arts as for the M.R.C.S., after having fulfilled a four years' curriculum (three-fifths general medicine and surgery, and two-fifths specially dental), and after a qualifying examination at the College of Surgeons for the L.D.S. diploma.—I am, Sir, yours truly,

Brook-street, W., July 1st, 1884. S. J. HUTCHINSON.

An Enquirer.—Our correspondent should have insisted upon the signing of the bond. As to the second part of the question, we think a man of fine feeling would be hardly likely to take advantage of the omission.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my paper on Perineal Lacerations, which appeared in your last issue, I am made to say, when speaking of the influence of these accidents in the production of puerperal septicæmia, that the latter is "a blood dyscrasia, having for its exciting cause an autogenetic and heterogenetic source," instead of an autogenetic *or* heterogenetic, &c. The insertion of this correction in your next issue will oblige, yours truly,

Nottingham, July 1st, 1884. GEORGE ELDER.

Lectures

ON SOME

IMPORTANT POINTS IN CONNEXION WITH THE

SURGERY OF THE URINARY ORGANS.

Delivered at the Royal College of Surgeons,

BY SIR HENRY THOMPSON, F.R.C.S.,

SURGEON EXTRAORDINARY TO HIS MAJESTY THE KING OF THE BELGIANS, PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, EMERITUS PROFESSOR OF CLINICAL SURGERY, ETC.

LECTURE V.

The Progress of Operative Surgery for Stone during the Present Century, with the most Recent Improvements in Lithotrity.

[THE lecturer commenced by remarking that amidst the progress made in art and science during the present century surgery was not less distinguished than other branches, of which the recent history of operation for stone afforded a complete illustration. A minute historical outline, commencing with the lithotomy practice, provincial and metropolitan, at the end of the eighteen century, described the advent of crushing, and the various improvements as they arose both in the cutting and the crushing methods as they competed with each other in the middle of the present century, until the lithotrite began gradually to supersede the use of the knife. It was interesting to observe how the idea of rendering lithotrity complete at a single operation had slowly been developed even from the time of Heurteloup, who had laboured hard to realise it, until its recent accomplishment in modern times. The lecturer continued]:—

Thus far it has been my object to make a rapid sketch of the general practice in relation to the surgical treatment of calculus in the chief capitals of Europe up to within about the last five years. But in 1878 Professor Bigelow of Harvard, U.S., proposed a further and a considerable advance in regard to the amount of crushing and aspiration which might be employed at a single sitting. Whatever the size or the nature of the stone, provided only that it was deemed to be within the compass of our power to crush, he advocated, on principle, that the whole should be removed at once, and no portion be permitted to remain, so far as the operator knew, for a second attempt. The principle enunciated was, that broken fragments remaining in the bladder were more injurious to it and more dangerous to the patient, by causing cystitis &c., than a prolonged sitting and a very considerable amount of mechanical interference expended on the task. This apparently bold proposal took many by surprise. It was not that the removal of a calculus at a single sitting was by any means a novelty in itself; small ones had been often thus disposed of. It was the proposal to deal with stones of very considerable size, and the prolongation of the sitting from a short term of minutes to one which might, according to the Professor's experience, occupy two hours, or even more, which naturally aroused much question. Nevertheless, I must avow that my experience of the value of removing all the fragments from a bladder when acute cystitis was set up had disposed me to receive the new doctrine with favour. Hence I at once put it to the test, and, without any change of instruments, proved its value in the first twenty cases which I treated by this method. Professor Bigelow had, however, made a further proposal—namely, that much larger and more powerful instruments, both lithotrites and evacuating tubes, should be employed than heretofore. These proved to be, for the most part, not only unnecessary, but to be sources of danger, especially in unpractised hands. The American surgeons had long been accustomed to use instruments in the treatment of stricture larger than those generally employed on this side of the Atlantic; and this fact has had the advantage of facilitating the production of Professor Bigelow's proposal. No doubt heavy and powerful crushing machines become absolutely essential to success in dealing with those exceptionally large calculi which have hitherto been relegated to the cutting operation, but to such rare examples only should they be applied.

A minor but not altogether unimportant proposal of Professor Bigelow was to change the name of the operation in future from lithotrity to "litholapaxy." His procedure, however, introduces no mode of action not employed before. Bigelow's achievement has been to demonstrate that crushing a stone, even if large, and removing all the fragments from the bladder at one sitting, is a safer proceeding than dividing the work between two, three, or more sittings. The value of this principle was perceived and insisted on, as we have seen, by Heurteloup thirty years ago, but he failed for want of anæsthesia. And it is a curious fact, too, as an illustration, if one were necessary, that the principle of evacuating the stone largely, as a part of the operation of lithotrity, is in no respect a novel one, that Heurteloup himself endeavoured, at the close of his career, to change the name of the proceeding on this very ground—viz., that he not merely crushed the stone, but that he also evacuated the débris artificially as completely as possible. The term which he desired to substitute to denote his method of crushing and evacuating the bladder, was "lithocénose," from λίθος, a stone, and κένωσις, extraction. Nevertheless he signally failed to do so, although the proceeding was really then, to some extent, a new one, and the original term, lithotrity, still remained as it does to this day. For there is an equal disinclination among many surgeons, foreign and English, to admit a similar change now, it being evident to everyone who knows anything of the history of lithotrity that evacuation by artificial means has been an essential part of the procedure for at least fifty-five years, and that this part has steadily grown in importance in a direct ratio with an increasing ability and determination to crush more largely than before. Five years of experience of lithotrity completed at a single sitting enables me to testify as fully concerning its capabilities perhaps as any other operator. It has been only partially tested at present on the Continent; entertained very cautiously at Paris; but received with gradually increasing favour at Vienna, where it is now the rule; but it is not in either place accepted for the largest calculi, and a cutting operation is preferred for those hard stones which weigh one ounce and a half and upwards in size. To this fact I shall hereafter refer, in presenting an analysis of my own experience of the one-sitting operation, which I have adopted in the last two hundred cases, to use round numbers, consecutively treated by myself. I propose first briefly to describe that proceeding which has appeared to me the most desirable in order to achieve successful lithotrity at a single sitting. We will commence by examining the instruments necessary for the operation, and then consider the method of employing them best adapted to effect our purpose.

In the first place, in respect of all instruments, we must recognise the importance of not inflicting any needless injury on the urethra and bladder, and should, therefore, always select the smallest lithotrites and evacuators which possess strength and capability adequate to crush and remove the individual calculus to be dealt with. And inasmuch as the great majority of calculi are small when first found by the surgeon, undue stretching of the natural calibre of the urethra is unnecessary for their removal, since no instrument need be used which exceeds the limit of that calibre. It is only when dealing with calculi of exceptional size, that instruments which distend the urethra to a considerable degree are to be employed.

Secondly, in dealing with a calculus of any size, but especially when large, it is important to employ instruments which are simple in construction and not easily liable to be deranged in action when employed in the bladder. The presence of débris in quantity, mixed with viscid mucus, perhaps with some coagulating blood, has to be reckoned on in circumstances which demand prolonged manipulation; and mechanical arrangements which work admirably in experiment with limpid fluids outside the bladder are not unlikely to fail when brought to the test of actual service. Simplicity in the construction of instruments is, therefore, to be attained if possible.

Let me suppose that the presence of a calculus has been determined by sounding in the bladder of an elderly male. It is almost certain that the note obtained and the resistance felt in making contact generally suffice also to convey an idea, approximately accurate, regarding the size and nature of the stone. As a rule, it is not so necessary now as it formerly was to make an exact diagnosis in rela-

Digitized by Google

tion to those particulars. When it was desirable to limit the application of lithotrity to calculi of, say, one inch and a half diameter, it was important to ascertain, by some easily managed method of measuring, what were their dimensions in every case. But now that the scope of lithotrity is considerably increased, all that is requisite to be learned is, whether the stone is an exceptionally large and hard one, and whether any unnatural narrowing of the canal is present; and both these points are almost sufficiently determined by an ordinary sounding in practised hands. At all events it is unnecessary to make any further examination for the purpose of diagnosis until the patient has been placed under the influence of an anæsthetic upon the operating table, the surgeon having full liberty to exercise his judgment and act as circumstances demand.

Invariably, as soon as the patient is thus prepared for operation, I pass a full-sized conical steel-plated sound—say about No. 15 (English), in order to determine that most important point of urethral calibre before touching the stone. If the urethra is healthy, and of course in the very great majority of cases it is so, the instrument has passed with perfect ease, and may probably be followed by No. 16 or 17 in an elderly adult, by which term I mean a man of sixty years and upwards. I am sure the urethra is more capacious in such patients than in those whose age is between thirty and fifty years. In these latter the urethra often resents any active distension, and the bladder also more readily becomes inflamed than in older patients. With a urethra admitting the easy passing of No. 16 almost anything is possible, and suffices for almost any calculus; but if I am dealing with one which weighs, in my judgment, about two ounces and more, I am glad to use larger sizes, and No. 18 I have never found it necessary to exceed. But if the stone is known to be small, No. 14 amply suffices, and there can be no reason for going beyond it. This is the size which was mostly used with the original instrument of Clover in 1866, and for all ordinary purposes answers admirably.

The lithotrite is next introduced. With small and medium-sized stones, a light instrument of the half-fenestrated pattern—that is, the lower portion of the male blade penetrating the female blade, which prevents the possibility of blocking by débris, while the upper portion is flat and crushes the stone into small fragments—is, I think, the best. This mode of construction is applicable for a wide range of size in calculus, answering for any one of uric acid below about an inch and a half in length. To accomplish the first fracture of such a one, or to crush into fragments a larger calculus, a fully fenestrated lithotrite is better. There are some old forms of blade which have been in use for fifty years, which cannot, I think, be excelled; so numerous are the patterns which have been employed, that it is difficult now to imagine a new design.

To proceed, supposing that a considerable quantity of débris has been made, the calculus being large, it is advisable to withdraw the lithotrite, to introduce an evacuating-sound and attach the aspirator, so as to withdraw the débris already made before crushing more. When this is removed, the same or a lighter instrument may crush the fragments into débris, before again using the evacuator. By this time, probably, the remaining portion is not considerable, and another introduction of the lithotrite, followed by another aspiration, very likely empties the bladder. If, however, a fragment or two are heard and felt to strike the end of the evacuator, yet do not pass through it, they are probably just too large to issue, and require another crushing before the task is completed. There is certainly now no difficulty in removing any last fragment from the bladder, the more powerful aspirators emptying the cavity so efficiently that no other instrument is necessary for the purpose; while by no sound is the last fragment found so well as by the evacuating catheter, against which contact of the fragment is certain to be felt or heard, through the action of the outrushing current of water.

In regard to aspirators, the original instrument of Clover, simple in the extreme, is a very good instrument, and requires only some modification to be as efficient as most of the modern ones. For my own aspirator I have provided a tap with funnel-shaped opening to the upper part of the india-rubber ball, by which to fill it, and to remove air accidentally introduced, which offers a decided advantage. Last year I attached to the end of the evacuator in the interior of the glass receiver a light wire valve, which while it admits any fragments to enter, renders their escape impossible; its action meantime being always visible to the operator.

After the operation the patient remains in bed, and rarely requires any special management, except sometimes that which a simple traumatic cystitis demands—namely, absolute rest in bed; occasionally the urine neutralised by potash; hot hip baths; mild diet; and watchful care that chronic retention of urine does not occur, or is not permitted to continue unrelieved; avoiding on the other hand undue or unnecessary interference by means of catheters. But of all the agents for rapidly removing subacute or chronic cystitis after lithotrity, nothing equals mild injections of nitrate of silver, the effect of which is sometimes almost instantaneous. I use only half a grain of the salt in four ounces of warm water at first, gradually increasing to a solution three times that strength, beyond which it is rarely necessary to go. Usually one application a day, sometimes two, will, in the course of three or four days, remove the painful symptom and produce clear and healthy urine.

My own experience of the system of treating all calculi but the very largest, by a single sitting of lithotrity, dates from shortly before Christmas, 1878; the first example being a case which I saw with Sir Spencer Wells, who was present at the operation. Since that time I have adopted the system of completing the operation at a single sitting for every case in which lithotrity appeared to be possible, with two exceptions only, to be described immediately. The total number of adult male patients on whom I have operated during the period referred to, a term of rather more than five years, is 211. Of these, fifteen have been by lithotomy, and of course forming the largest and worst cases, with seven deaths. There remain, therefore, 196 cases treated by lithotrity. One of these was a Portuguese gentleman, No. 535, in my collection before you, to whom Mr. Clover thought it prudent to administer chloroform only for a very limited time. He had five sittings to remove a stone weighing no less than 787 grains, and made a good recovery. The other exception was that of a large oxalate of lime calculus, No. 538, which at that time I preferred to crush in four sittings. The débris weighs 640 grains; he is now perfectly well. Every one of the remaining cases, 194 in number, has been treated at a single sitting, making a total of 196 cases of lithotrity at a single sitting, with 10 deaths, or just 5 per cent. Total of 211 cases of adults by the two operations, with 17 deaths, or 8 per cent. The mean age of these patients was over sixty years. And this is a result which hitherto has, I need hardly say, not been approached by any other mode of treating calculus in the adult. This subject, however, will be illustrated more fully in the succeeding lecture, when I shall present the results of my entire series, embracing upwards of 800 cases by the two operations.

I have crushed several stones of uric acid, and one of oxalate of lime, considerably upwards of an ounce in weight. The largest uric acid calculus I removed at a single sitting weighed two ounces and three-quarters, and occupied me seventy minutes. The patient was seventy years of age, and made a capital recovery. I cannot speak too highly of the results thus attained. Indeed, nothing need be added to the figures I have adduced above, which exceeded any expectation I could have previously formed as to the success of operating on men upwards of sixty years of age, with stones of all sizes. In conclusion, I think we must admit that the operation of lithotrity at a single sitting bids fair to supersede lithotomy for the adult calculous patient in all cases except those in which the stone is of rare and exceptional size.

ON CHARCOT'S JOINT DISEASE.

By W. HALE WHITE, M.D., M.R.C.P.,
SENIOR DEMONSTRATOR OF ANATOMY AT GUY'S HOSPITAL.

DURING the last few months the subject of Charcot's joint disease in association with locomotor ataxy has come before the Pathological and Clinical Societies three times, and on each occasion observers of great note have been found to state their scepticism as to the existence of any definite arthropathy such as Charcot describes. Thus, when Mr. Arbuthnot Lane brought his paper on Mollities Ossium, Rheumatoid Arthritis, and Charcot's Disease before the Pathological Society,[1] both Mr. Hulke and Dr. Goodhart seemed to consider that all the cases which had from time to

time been shown them as examples of Charcot's disease were really rheumatoid arthritis; and when Mr. Clement Lucas read his paper before the Clinical Society,[2] Dr. Moxon stated his belief that Charcot's joint disease was only rheumatic arthritis occurring in patients affected with locomotor ataxy. If no others than the three gentlemen just mentioned were doubtful of the entity of the disease, the fact of their hesitation to accept it would make it worth while to inquire into the exact position of the question as to whether or not it is a distinct malady. It seems to me that three views may be held with regard to it. In the first place, there is that of Charcot and his followers, who state that the joint disease is a distinct specific arthropathy peculiar to locomotor ataxy. Secondly, there is the view that it is an ordinary arthritis, somewhat modified by the conditions of the patient, but dependent upon nerve lesion, as are the arthropathies found after injuries to nerves. Thirdly, there is the view that it is merely a rheumatic or some other form of arthritis which has occurred in an ataxic patient, the coincidence of their occurrence being pure chance.

To take Charcot's view first. We are here dependent entirely upon the clinical and post-mortem characteristics, because up to the present time no one has been able to state in what part of the nervous system the joint centre, if there be such a spot, exists. Charcot was at first inclined to place it in the anterior cornua, but this theory has been abandoned because post-mortem experience has shown that the disease may be present without any change in the anterior cornua being demonstrable. Then the hypothesis has been put forward by Buzzard that there is in the medulla an arthritic centre which becomes affected in locomotor ataxy. He urges in favour of this view the frequent association of gastric crises with joint trouble; but although this is an ingenious hypothesis, it is as yet hardly certain enough to allow us to argue that because there is a joint centre in the medulla, therefore we may look for joint lesions of a specific nature in locomotor ataxy. It has also been urged that the lesions of the peripheral nerves discovered by Pitres and Vaillard are the cause of the arthritis; but against this is the fact that in some cases in which the joint trouble has been present there has been no peripheral nerve change. Thus we see, as we are unable to argue *a priori* from the fact of a nervous cause for the joint troubles in locomotor ataxy being constantly present that therefore they are probably peculiar to that malady, the view we are now considering depends entirely upon the clinical and post-mortem characteristics of the disease. The clinical symptoms are, according to Charcot,[3] briefly these:—Without appreciable external cause in the slightly advanced period of the locomotor ataxy this arthropathy is developed; the first phenomenon discernible is extreme tumefaction, which is formed by a considerable hydarthrosis, and an engorgement presenting a hard consistence; usually there is no fever, pain, or cracking sound. At the end of some months the swelling disappears and all returns to the normal state, or in other cases serious disorder, such as crackings, dislocations, &c., remain in the joints; the order of frequency is knee, shoulder, elbow, hip, wrist. At the meetings of the Pathological and Clinical Societies just referred to neither Mr. Hulke, Dr. Moxon, nor Dr. Goodhart—all distinguished clinicists with a large field of observation—knew anything of this train of symptoms. In thirty cases of locomotor ataxy which he had most carefully observed, Dr. Moxon had not detected any specific arthritic changes. Charcot, however, found five patients presenting such changes among fifty examined. The following quotation from Senator[4] will, I think, show that he is not certain that the arthropathy of locomotor ataxy is a distinct disease:—"Charcot and his pupils subsequently drew attention to the occurrence of peculiar articular swellings in locomotor ataxy and other forms of paralysis ..... It is quite true these articular swellings did not invariably present the characters of arthritis deformans; they often set in with abundant effusion into the joint, a symptom quite foreign to the latter disease; in other cases, however, the characteristic morbid changes developed themselves either at once or after a time." Further on he says: "To distinguish arthritis deformans at this early stage from the articular neuroses there are hardly any criteria." Ball[5] is very emphatic in pointing out the distinctions between the two maladies, but the impression one gets from reading his article is that there are many similarities. Thus he records two cases in which are presented heat and redness of the joint, and other connecting links might be found in his descriptions.

We have heard a good deal about the frequency with which these cases have been overlooked by surgeons, and there is the story told of a patient who, although suffering from Charcot's joint disease, was shown to the candidates at one of the examining boards as a case of rheumatoid arthritis; but surely all this tells strongly in favour of the view that there are no distinct clinical characteristics of Charcot's disease, for those surgeons who are accused of having made such errors, seeing, as they do, a large number of cases of rheumatoid arthritis, would have been the first to set aside these cases as peculiar had they really been so. The case that was used for examination purposes cannot have been so very out of the common if it passed through several surgeons' hands as a case sufficiently typical to show to candidates.

Turning again to Charcot's own account of the disease, we find that he admits "the analogy existing as regards cracking sounds, the osseous tumefactions, &c." It is perhaps difficult to determine exactly how much is included under that "&c.," for a reference to his list of points of distinction between the two diseases will show that there is hardly a single symptom which is not in some measure common to his disease and an ordinary arthritis; thus pain, thickening of the synovial membrane, and hydarthrosis may be present in both. I have seen lately six cases of joint disease in locomotor ataxy, all of which were considered to be examples of Charcot's disease by some of those who had seen them, although not one of them was universally allowed to be an example of that malady; but I have never seen a case of joint disease in association with locomotor ataxy which was universally allowed not to be Charcot's disease. This is, of course, not logically conclusive, but still it is some evidence that whenever a patient is discovered with locomotor ataxy and a joint lesion somebody will be found who thinks it is a peculiar arthropathy. Although one or even two of the six cases above-mentioned were not typical instances of ordinary arthritis, there was not a single one that I should like to say could not be regarded as some form of that disease.

When we come to consider the pathological aspect of the joint lesion, it is evident at once that the peculiarities of Charcot's disease are not very striking; in fact, he himself says, "On the whole, anatomically speaking, our arthropathy is included in the group of dry arthritis," and certainly this is true of the specimen he presented to St. Thomas's Hospital Museum. I do not think that anybody on being shown that would say, without knowing the history of the case, that there was anything about the bone to distinguish it from a specimen of rheumatoid arthritis. The piece of the top of the humerus he presented to the Museum of the College of Surgeons (No. 1921), shows that the head of the bone has entirely disappeared. A smooth and partly eburnated surface is left, surrounded by bony outgrowths. It will be noted that these last two points are most characteristic of rheumatoid arthritis. This specimen is in a case with many other dried ones of joint mischief, and thus there is an excellent opportunity of noting the points in which it resembles them. The only other example I am acquainted with is the pelvis, which I exhibited to the Pathological Society, and which Prof. Charcot was kind enough to examine for me. He pronounced it to be a rare form of the arthropathy he associates with locomotor ataxy. Now, this specimen undoubtedly presents a very unusual condition of things; the slight formation of new bone, the rarefaction of the normal bone, and the great deepening of the acetabula as a result of this, and the pressure inwards of the heads of the femora, go to build up a pelvis quite unlike anything which any Englishman to whom I have shown the specimen has seen. It was taken from a dissecting-room female subject; there is therefore a strong probability that it came from some infirmary bedridden subject. One thing is quite certain—namely, that she was in some public institution with a resident medical officer. Now, surely, considering how everyone is on the alert to find a case of Charcot's joint disease, had this patient presented symptoms of locomotor ataxy, she would have been recorded in one of the journals, or we should have heard of it in some way or another. It should also be noticed that there was some slight evidence of formation of new bone, although the chief characteristics were undoubtedly the absence of stalactites and the predominance of the wearing away process; but

considering that we have no evidence of locomotor ataxy, that both hips (which in Charcot's disease are but rarely affected) were here diseased, that there is some evidence of new bone formation, that the bones in old people are very liable to become light and thin, and, lastly, that in old people morbus coxæ senilis, which assumes divers forms, is common, is it not perhaps better to postpone definitely calling this specimen one of locomotor arthropathy, as our knowledge of this disease is still in its infancy?

Specimens 1922 and 1922A in the Royal College of Surgeons Museum show how extremely difficult it is to be sure of any distinct characters in the joints said to be affected with Charcot's disease. No. 1922 consists of the bones of the right upper extremity; they are all very wasted and much thinned, the shoulder-joint is destroyed, the head of the humerus gone, and the wrist bones are much atrophied, but the bones are no smaller than I have seen in an upper extremity which has been spastically contracted and disused for some years. The left knee-joint shows no production of stalactites, but the bones are so thinned that the first thing that suggested itself was that, whatever disease the patient suffered from, she must have been unable to use her leg for some time. In the catalogue is the following: "Joint changes symmetrical; those most like locomotor ataxy occur in the shoulders." The writer then goes on to say that the joint changes present "just the features of Charcot's joint disease. It may be that the woman is ataxic, and in a poor bedridden cripple it is not easy to decide this point; if, however, it be thought probable that ataxia is present, the case still remains chiefly one of general rheumatism, for the joints are or have been almost all affected, and with remarkable symmetry, whilst none are positively dislocated." Surely if a case presents just the features of Charcot's joint disease but still remains chiefly one of general rheumatism, there cannot be much distinction between the two diseases.

One need not proceed in showing that it is doubtful whether this disease is a pathological entity, because Charcot himself allows that it is not, the only points he urges are that in it the productions of new bone are slight, whilst the wearing away is excessive. I have tried to show that these two points in the three specimens I have seen are not so characteristic as to be very distinctive, and I hope to show that they may be accounted for in a simple way. I would refer the reader who is interested in the subject to the descriptions[6] by Féré, and Charcot and Féré, of the specimens in Paris. Here the majority of the cases undoubtedly show the two points just mentioned; nevertheless, there are some which are not much worn away and some with new stalactites. Mr. Arbuthnot Lane has already shown in the paper referred to that in a patient with most of the joints affected with rheumatoid arthritis the jaw may present such characters as to make it indistinguishable from Charcot's arthropathy. This speaks for itself.

Let us consider next the hypothesis that this arthritis occurring with locomotor ataxy is really the same as is produced in joints after injuries to nerves. Weir Mitchell[7] says it is quite evident that injuries of the spine, diseases of the spinal cord and of the brain, and wounds or any form of lesions of nerves, are capable of developing in the joints inflammatory conditions, usually subacute, and which precisely resemble rheumatic arthritis in their symptoms and results, so that no clinical skill can discriminate between the two. The same author again[8] says that the arthropathies due to nervous disease are so difficult to tell from rheumatism that they lend support to the theory that it is primarily a nervous disease. J. K. Mitchell, nearly fifty years ago, in the *American Journal of Medical Science*, also pointed out that obvious spinal cause may produce rheumatism characterised by heat, pain, redness, and tumefaction. It has also been shown by Gull that diseases of the cord will produce joint mischief. Ziemssen allows that injuries of the nervous system may be the cause of joint lesions. Charcot[9] himself gives several cases, such as one of a tumour of the right hemisphere, in which the joints of the opposite side were affected; he also shows that this cannot be due to a descending lesion, because it comes on too early, and for the same reason it cannot be due to functional inertia. Thus it appears there is no doubt that nerve lesions will produce joint disease indistinguishable from other well-known forms of arthritis. All authors who have written upon these arthropathies are of opinion that they are produced by inhibition of the trophic influence of certain nerves. There are perhaps some who still do not recognise the existence of trophic nerves, but at present the evidence is in support of their existence. Foster, who is always very cautious, considers that facts turn the balance in favour of trophic nerves. We must therefore allow the possibility of joint changes due to nervous lesion in a malady presenting such widespread alterations in the nervous system as does locomotor ataxy, but it is difficult to see the advantage of surrounding them with a halo of mystery; they may not be perhaps so acute as some nervous arthropathies, but still if they are due to a nervous change they must belong to that class, and t can only result in confusion to separate them from it. They must also be inflammatory; it is always allowed that the destruction of trophic influence results in inflammation of a part; true it is that it may be modified by various circumstances. Thus in the case of a joint inflammation not much new bone may be thrown out, but still it will belong to the same group. There can, it seems to me, be little doubt that not nearly all the cases that are described as Charcot's disease are really examples of an affection of the joints due to the destruction of some nervous influence; nevertheless, as I have just stated, we must allow that such is possible, although the admission lands us in considerable difficulties. Thus, if we allow that there is a trophic centre somewhere in the central nervous system which presides over the joints, some affection ought to supervene in them whenever the path from the centre to them is interrupted; for example, if the centre be in the medulla, as Buzzard supposes, whenever the nervous tract going from the medulla to the knee is injured we ought to get changes in the knee-joint, but we do not. The subjects of fractured spines may live for months without joint changes; severance of the cords in animals leads to no such result. Undoubtedly sometimes destruction of the cord will lead to joint mischief; but if the theory be true, it ought always to do so; just as section of the vagus always makes the heart go faster. The only way out of the difficulty is to imagine that the trophic influences descend in the sympathetic cord; this may be so, but at present we have no evidence of it.

The last of the three possible views is that the cases under consideration are ordinary rheumatic or other forms of arthritis occurring in ataxic patients, independently of their nervous disease, although sometimes modified by the conditions enforced by it. This view will, I imagine, be found to satisfactorily explain a very large number of cases called Charcot's joint disease, whilst for the remainder we may invoke the aid of the theory which refers them to some tropic nerve lesion. We are in fact driven to it by exclusion, and it is supported by the numerous resemblances to chronic rheumatic arthritis which have already been shown to exist in many cases of so-called Charcot's joint disease. When it comes on late in the ataxic it may be, as Volkmann has suggested, a traumatic arthritis, for this condition must be prone to occur in patients always flinging their legs about, and, once set up, it is very unlikely to have much chance of getting well. In the bedridden cases there are all the conditions requisite for the production of this arthropathy. It is well known that joints but little subject to use are very liable to disease. Thus I know of a gentleman who was confined to his bed for some weeks on account of a severe strain of the hip. He first got up for a short time one evening, and on waking the next morning his knee-joint presented exactly the characters ascribed to Charcot's locomotor arthropathy, but this change was obviously merely due to the slight use to which he had put a joint which had been for a long time disused. Then, again, with regard to the thinning of bones and fractures. One has only to spend a week in a large dissecting-room to see that old bedridden people are peculiarly liable to have their bones very thin, and hence also very liable to fracture of them. The supporters of the view of the specific entity of the locomotor arthropathy admit that it is very rare; thus, Charcot himself puts it at one in every ten cases of ataxy, and this is a high proportion. We have just shown that the examples which occur late in the malady may be easily explained, without necessarily supposing them to be peculiar to ataxy; so that we have only those few left which come on in the early period of the disease, and when we remember that in these cases sometimes the joint may be red, sometimes there may be fever, sometimes there may be much pain, and sometimes effusion into the joint, it does seem, considering

the avowedly few number of cases and the numerous connecting links, somewhat rash to maintain that these are examples of an arthritis peculiar to locomotor ataxy. Then, again, in order to prove the case for a peculiar arthropathy, it must be shown that ataxics are more liable to joint trouble than other people, for unless they are less liable to rheumatic arthritis and common joint diseases than the rest of mankind, they will have these troubles together with their special ones, so that a larger percentage of ataxics than of ordinary people will have joint disease. But this has never been shown to be so, and my impression is that ataxics would not be found to be more liable to joint disease than any other class of people. But we are told post mortem the difference is to be seen, inasmuch as the wearing away process predominates over the production of stalacutes. The conditions under which ataxics are placed will, it seems to me, account for this, which, as shown above, is not always very marked; their whole vital power is lowered by the restraint imposed upon them by their malady. Thus they are often confined to bed, and various depressing complications are liable to supervene. Is it, then, strange that the new bone should not be thrown out very abundantly? The excessive wearing away can easily be accounted for when we remember the extreme thinness of the bones. If we look to other diseases, we see how the general condition of the patient modifies their course; for example, if a patient be in a very low condition, the granulations on an ulcerating surface will be small and grow slowly, whilst if he be in robust health they will be abundant and grow quickly. If in this case, why in that of the joint mischief may not the condition of the patient be used to explain a seeming peculiarity?

Further observation may show that Charcot's disease is a condition specially associated with locomotor ataxy. My object has merely been to point out that this has not been yet completely proved, and to present the arguments against it; also to suggest that whilst some cases of Charcot's disease may, like other nervous arthropathies, be due to the alteration of some trophic influence, a large number of cases that have been brought forward as a special disease are ordinary and well-known forms of arthritis, possibly somewhat modified by the condition of the patient.

St. Thomas's-street, S.E.

CHARCOT'S JOINT DISEASE

(ATAXIC ARTHROPATHY; TABETIC ARTHRITIS).

By PHILIP H. KIDD, M.B. EDIN.,

ASSISTANT-SURGEON TO THE HARTLEPOOLS FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.

THE comparative rarity of this disease, its recent discovery, and the obscurity that still hangs over many points alike in its pathology and its clinical picture, justify, I think, the somewhat detailed description I have given of the following case:—

Mr. ——, between forty-two and forty-three years of age, a small shopkeeper, began about a year and a half ago to complain of pains in his thighs and the lower part of his abdomen, which he compares to being slit with a knife, and for the relief of which he used to curl up his left leg, so that his heel touched the trunk on the same side, and take long walks. Shortly afterwards he noticed a crackling sound in his left thigh whenever he moved it, and this was succeeded by swelling over the region of the hip-joint, which seems to have reached as far as half-way down the thigh on the outside, and was accompanied by a more circumscribed swelling in front of the joint, thus showing, I take it, that it was a true effusion into the cavity of the articulation. He then called in the medical officers of the Association, who prescribed for him, and painted his hip with iodine. Treatment was followed by subsidence of the swelling, but the crackling sound remained, and the pains descended into his leg, and about that time he also noticed wasting of the leg. He was able soon afterwards to get about by means of a stick, and attendance on him ceased for some months. On March 8th last, he first noticed the crackling in the right hip, unaccompanied this time by any swelling, and as this increased, and the corresponding leg and thigh began also to waste, he asked for further attendance.

On April 4th I saw the patient, and elicited the following facts. He has always lived a steady, quiet life, and has a comfortable home; has had no form of venereal disease, nor suffered from nocturnal emissions; has always been a healthy, active man, and the only point in his history is that about seven years ago he was knocked down by a frightened cow in the street, and was brought home looking, his wife says, "just like a corpse." She avers that he has never been the same man since. He has been married fifteen years and had nine children, of whom five are alive and all healthy. He has never indulged in spirituous liquors, though his father is a heavy drinker. His family history is good.

The patient when I saw him was a good deal emaciated, had an anxious expression, and a dusky, unhealthy complexion. There was no evidence of any pulmonary or cardiac disease. On moving either hip loud crackling sounds were produced, which were propagated down the thigh. He complained of pains like being slit with a knife down the legs and in the lower part of the abdomen; sometimes these pains passed up into the epigastric region, and then he lost his appetite for a day, but there was never any vomiting or other gastric disturbance of any kind. There was no girdle pain. The patellar tendon-reflex was entirely absent in both limbs; in sitting on the bedside to have this tested his right foot swung at a normal angle to the leg, while in the left limb the dorsum of the foot and of the leg were in the same straight line, and the great toe curved downwards to the ground; the cutaneous veins were noticed to be engorged in both lower extremities, especially so in the left. Tactile sensation was fairly correct in both soles, though it was delayed; but there was well-marked analgesia except in one spot in the waist of the foot. The character of the gait was too much masked by the double hip-joint disease to be trustworthy; but he did not seem to have the usual feeling of padding in the soles of his feet; he had never noticed any difficulty about walking in the dark, but soon began to totter when standing with his eyes shut. The glutei muscles were not atrophied, and when standing they were in a condition of spasm, which was probably due to the great laxity of the ligaments. He had now no skin disease, but last summer while under treatment he said he had an eruption on his chest, which seemed to have been a diffused redness not marked by wheals, vesicles, or papules, and which came and went. When it was fully out it was accompanied by intense itching and burning, but did not seem to have had any relation to, or connexion with, the slitting pains. The gastric, intestinal, and laryngeal functions were normal. For three weeks previously his urine had passed away from him while sitting or lying down; the first thing he knew about it was the wetness of his shirt. The vision of his right eye was about normal, but with his left he could not make out No. 20 Snellen's types at any distance. The pupils were both a good deal contracted, but retained a feeble amount of accommodation to both light and convergence. They responded less readily to light than to convergence, so that the Argyll-Robertson phenomenon might be said to have been partially developed. With the ophthalmoscope the fundus of the right eye appeared to be normal; the fundus of the left was pale, the vessels were small and tortuous, and the optic disc was atrophied.

There could, I think, be no doubt that this was a true case of locomotor ataxia, and of the joint disease which sometimes accompanies it. The salient points seemed to me to be the particular joints affected; the appearance of the grating prior to any effusion; the great laxity of the ligaments in the ataxic limbs and the early date in the history at which this would seem to have existed; the absence of *crises gastriques;* the position of the left foot when pendulous, as somewhat complicating the diagnosis; and the differential diagnosis from chronic osteo-arthritis in such a case as this where the locomotor ataxia was not previously known to exist. As regards the question of diagnosis, Dr. Byrom Bramwell[1] gives three criteria—(1) that this disease is more acute; (2) that in chronic rheumatic arthritis the smaller joints and the hip are most frequently affected, whereas in locomotor ataxia the knee and shoulder are most often involved; (3) the presence of liquid effusion and dislocations. I have not found any of these criteria of very much help, for my case has lasted very nearly a year, probably quite, and, beyond the fact of another joint having become involved, not much progress seems to have been made. As to the joints affected, besides this one, I have access to the records of only eight cases. In the case shown by Mr. Page to the Medical

[1] Diseases of the Spinal Cord, p. 221.

Digitized by Google

Congress of London[3] the tarso-metatarsal joints were the seat; in both Mr. Macnamara's two cases,[4] shown at the same time, the right hip was affected; at the same time Professor Charcot demonstrated two cases; in Berthelot the left knee was first attacked, though the right hip eventually did not escape; in Cressy there was disease of both hips. Dr. Hale White's[4] post-mortem case was of both hips; Mr. Lucas's case[5] showed the right elbow and foot affected; in Mr. Raven's[6] the knee-joints were the first attacked. With such a record Dr. Bramwell's view can scarcely be accepted; indeed it would seem that the hip is rather a favourite seat of the disease. In both Mr. Macnamara's cases, as in mine, the effusion was but a fugitive phenomenon, and dislocations are not always seen apparently till a later period. The most trustworthy criteria seem to me to be the absence of pain in the joint itself, which must be carefully distinguished from the lightning pain in the limb, which may easily be mistaken for rheumatic; the laxity of the ligaments; and any evidence of disease of the nervous system. A careful inquiry will then probably set the matter at rest by showing the existence of ataxia.

With reference to the true nature of the disease and its etiology, I would for the present be content to look on it as depending on want of nutrition, and referable to the same predisposing causes, at least, as the laxity of the ligaments and as the perforating ulcers occasionally seen in ataxic limbs. The cause of this want of nutrition I am inclined to agree with Dr. Althaus in ascribing to peripheral neuritis; Dr. Charcot's theory of affection of the anterior cornua would seem to be upset by more recent cases, and for Dr. Buzzard's bulbar theory, I know of no evidence; besides, a spinal lesion does not seem to be a necessary factor of locomotor ataxia itself.[7] As to whether the disease is a true atrophy or a low and modified form of inflammation, I must leave to pathologists to discuss; my point of view is from the bedside, not the post-mortem room.

I cannot conclude this report without thanking my late senior colleague, Dr. Johnstone Weir, both for giving the case over to me to study directly he knew my diagnosis, and also for kindly furnishing me with the report on the eyes; his experience gained while resident at the Glasgow Eye Infirmary renders his report accurate and trustworthy.

West Hartlepool.

ON CYSTS AND CYSTIC TUMOURS OF THE BREAST.

By HENRY T. BUTLIN, F.R.C.S.,

ASSISTANT-SURGEON AND DEMONSTRATOR OF DISEASES OF THE LARYNX, ST. BARTHOLOMEW'S HOSPITAL.

No. III.—CYSTIC TUMOURS.

THE two preceding papers have been devoted to the consideration of those diseases of the breast in which the formation of cysts played the chief or, in some instances, the only part, and in which there was no real tumour external to the cyst, although some of them, the glandular cysts especially, contained intra-cystic growths. In this, the last paper of the series, I propose to speak of the tumours which contain cysts, and particularly of those tumours to which the name of sero-cystic has been given.

I have recently described in the System of Surgery and in the fourth volume of the American Encyclopædia of Surgery the general relations between cysts and solid tumours, and I need only point out now that cysts may form in tumours of the breast just as they form in the natural tissues of the breast; they may be glandular or connective tissue (lymphatic). They are far more common in the connective tissue tumours, fibromas, and sarcomas than in the carcinomas; and, contrary to what might be expected, cysts of glandular origin are far more common than those of connective tissue origin. When, however, the frequency, nay, the almost invariable occurrence, of glandular structures in the connective tissue tumours is remembered, this fact will not appear so singular. The manner of the formation of the glandular cysts in the connective tissue tumours is precisely similar to the manner of their formation in the normal breast. Fluid is secreted into the interior of the acini and small ducts which form so striking a part of the structure of the tumours. The fluid cannot escape because there is no apparatus provided for its escape, the ducts which connect the secreting structures of the tumour with the main ducts of the gland, if they still exist, are obstructed, and consequently worthless; the fluid, therefore, must either be absorbed or must distend the cavities into which it has been poured. When a connective tissue tumour, of whatever kind, contains cysts, the cysts are much more prone to become the seat of intra-cystic growths than are the cysts which develop in the normal breast; for, in addition to the growths which spring from the wall of the cysts into their interior, the tumour, constantly increasing, tends to increase in the directions of least resistance, and thrusts its new growths into the cavities of the cysts, pushing the wall before them, distorting the shape of the cysts, and leading by pressure to absorption of part or of the whole of the fluid. In many such tumours there is thus a continual struggle for place between the solid and fluid constituents. The glandular apparatus pours out fluid, the fluid widens a cavity for itself, the solid puts forth new solid, the new solid is projected into the interior of the cavity, and the cavity is often scarcely formed before it is filled up and obliterated by solid growths. In the carcinomas the manner of development of cysts is probably not always that which has been described. The impulse to the development of new cells in the interior of the glandular acini and ducts is so strong that it is more than probable that new cell formation precedes the development of cysts, and that the cysts are, in many instances, due to the degeneration of the central cells of a cell mass (in the manner described by Mr. Eve).

I have in my possession notes of sixty-six cases of cystic tumour of the breast, many of which were examined by myself, and all of which were examined microscopically. In all these cases the cysts were of more or less considerable size, so as to form a striking feature of the disease. Fifty-six were connective tissue tumours, nine were carcinomas. One was an adenoma. The connective tissue tumours were thus divided: twenty-five sarcomas, eighteen fibromas, six adeno-fibromas, seven mixed connective tissue tumours. For all practical purposes the fibromas and adeno-fibromas may be included under one heading, for there is almost never a fibroma which does not contain glandular structures, and the rather larger proportion of glandular structures which the adeno-fibromas contain does not in any respect affect the course which they pursue. The mixed connective tissue tumours were composed of fibrous, mucous, and sarcomatous tissues in varying proportions, so that some of them might be regarded as fibrifying sarcomas; others as fibromas which had not completed their development. They invariably contained glandular structures, sometimes in considerable quantity. Anatomically, it appears from these sixty-six cases that almost every kind of tumour which attacks the breast may be cystic, and that there is not any one variety of tumour which especially deserves the name of cystic. Nor, on the other hand, are there any of these tumours which occur in the breast only in association with cysts—in other words, only in a cystic form. Clinically, the facts in my possession are defective, for few of the cases have been followed long after operation. Still, the facts which have been observed all tend so show that the life history of these tumours is dependent on the nature of their solid constituents, not on the size or number of the cysts which they contain. Thus, the further history of seven cases of sarcoma is recorded. In four of these very considerable operations were practised, the entire breast having been removed freely at the first operation; no recurrence took place in any of them, although one of the patients died between two and three years later of cancer of the other breast. In the other three cases recurrence took place in two of them after removal of the tumour; in the third after amputation of the breast. The last was evidently a very bad case; the tumour had only been noticed a few months, it had grown quickly, and the recurrence took place almost before the wound of the operation was healed; no further attempt to remove it appears to have been made. The recurrences in the first and second cases were numerous, continuing till one patient died from the effects of the fourth operation, and until the last report in the other case, full fourteen years after the first tumour was removed. It is interesting to note in confirmation of Dr. Gross's statement, that sarcomas of the breast do not affect the lymphatic glands, that the only instance in which there was enlarge-

ment of the axillary glands in connexion with a cystic sarcoma was one of these seven; the glands were not removed, and when the patient was seen four years later the enlargement had subsided completely. Of the twenty-four cases made up by grouping together the fibromas and adeno-fibromas the further history of six is recorded. In five of these there was no recurrence, whether the operation had been merely a removal of the tumour or amputation of the breast. In the sixth a second tumour appeared near the site of that which had been removed about six months previously, grew for a few months, then ceased to enlarge. It does not appear to have caused any trouble, and was therefore not removed. Three of the patients with mixed connective tissue tumours were heard of long after they had been operated on. The results of the operations were, as might have been expected, somewhat different. In two of them there had been no recurrence; in the third the breast had been removed completely by a second operation, and when the patient wrote in reply to an inquiry from myself she was again suffering from recurrence. Where the tumours are of so mixed a structure, containing various modifications of fibrous and mucous tissue and a larger or less amount of embryonic tissue, it is absolutely impossible to offer a certain prognosis. The cystic carcinomas presented no other unusual characters except the cysts; their course was precisely similar in all respects to that of an equal number of carcinomas without cysts.

From a study of the various cystic tumours of the breast I cannot but come to the conclusion that the cysts, although they produce a marked alteration in the physical characters and are associated with rapid growth of the tumours, are of absolutely no importance so far as the life-history of the tumours is concerned. The cysts, however large and numerous they be, neither diminish nor increase the capacity of the tumour for evil. A cystic fibroma is not more formidable to life, except in so far as it is generally larger, than is a fibroma without cysts; a cystic carcinoma or sarcoma is not less likely to recur than is a carcinoma or sarcoma without cysts. The cysts may almost be regarded as an accident in the development of a tumour of the breast, and, seeing that almost every variety of tumour of the breast may contain them, it might further seem that any and every tumour of the breast might, at any period of its development, become cystic. Such, however, is not the case; the same rule with regard to age prevails for cystic tumours as for simple (glandular and connective tissue) cysts; they are a disease of women over forty years of age. Only two of the sixty-six patients of whom I have spoken were under thirty years, and in both these cases the cysts were what are termed soap-cysts, a modification of milk-cysts, and therefore essentially cysts of the breasts of young women. Fifty-six patients were over forty years of age, and of the remaining eight who were between thirty and forty years, four were between thirty-seven and forty years. The relation of cystic tumours to age is much more difficult to explain than was the relation of simple cysts to age.[1] Fibromas, adeno-fibromas, and sarcomas occur in the breasts of women of all ages, and the fibromas containing glandular structures are more common in the breasts of women under than over forty. Nay more, tiny cysts are common in these fibromas or adeno-fibromas of young women. I have several examples of tumours containing such tiny cysts, some of them scarcely visible to the naked eye, yet most of them containing intra-cystic growths. Microscopically, neither the cysts nor the intra-cystic growths differed from the cysts and intra-cystic growths in the larger and decidedly cystic tumours. Surely it is a marvellous circumstance that only women of a certain age appear to be capable of developing those large and numerous cysts which make so striking a part of many tumours of the breast.

The foregoing remarks are entirely opposed to the teaching of the principal text-books of surgery at present employed in our schools, in which the classification and description of most of the tumours of the breast are those used fifty or more years ago. The books have been compelled to adopt largely the anatomical classification of tumours in the chapters which are devoted to the general account of these diseases; but they have not yet carried this classification into the chapter devoted to tumours of the breast. This is much to be deplored: first, because the student is perplexed by being obliged to apply a quite different classification to tumours of the breast to that which he has used elsewhere; second, because the descriptions of the tumours and the very terms which are applied to them draw his attention from the most important features of the diseases and fix it on those characters which are indeed most striking but are comparatively unimportant. As a teacher of surgery in a large school I constantly feel this difficulty in regard to tumours of the breast. I would fain teach as I believe and make my teaching harmonise with that of the best modern works on pathology of the last twenty years; but the fear lest such teaching should clash with the opinions of the examining boards has hitherto prevented me from doing so.

ON

THE DIAGNOSTIC VALUE OF WESTPHAL'S SYMPTOM IN SOME UNUSUAL FORMS OF SPINAL DISEASE.

BY JULIUS ALTHAUS, M.D., M.R.C.P.,
SENIOR PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.

Loss of the knee-jerk is found in all cases of uncomplicated tabes in which we have to do with sclerosis of the posterior columns in the lumbar portion of the cord; and this symptom is of the greatest diagnostic value, more especially in those by no means unfrequent cases where the other symptoms of spinal disease are somewhat indistinct, and it may be overshadowed by signs which are apt to be referred to stomach and liver derangement, or are believed to be owing to gout, hypochondriasis, and other diseases. In the following case the diagnosis of gout had been made by several experienced practitioners, and it was chiefly the presence of Westphal's symptom which enabled me to recognise the existence of tabes.

A stockbroker, aged fifty-nine, married, but childless, consulted me in October, 1881. He complained of being eaten up with the gout, and of having the most fearful gouty pains in his head, chest, back, loins, stomach, and, worst of all, in the bladder. He had had syphilis fifteen years ago, but had not shown any symptoms of it during the last twelve years. He had lately been treated with citrate of potash, lithia, and colchicum, but without relief. The peculiar description which he gave of the pains to which he was the subject made me suspect tabes; and on examining his legs, I found the knee-jerk absent, which threw at once a flood of light on the nature of his malady. I then examined him for other symptoms of tabes, and found that he had Argyll-Robertson's symptom of reflectory rigidity of the pupils, staggered on standing with his eyes closed, had lost the sexual power some years ago, and suffered frequently from incontinence of the bladder and bowels. He had regular *vesical crises* from time to time, when he would be seized with severe pain in the bladder, chiefly at night, and constant desire to pass urine. On some occasions he had been called out of bed more than sixty times in the course of a single night, and would each time pass only a few drops of urine, in great agony. He had similar *rectal crises*, and would soil himself five or six times in the course of a night. The upper extremities were not affected, with the exception of an area of numbness in the right ulnar nerve.

In July, 1882, Dr. Philpot, of Croydon, asked me to see a patient with him, whose case had been diagnosed as "hypochondriasis with loss of nerve power" by several physicians; and although I was led to look for tabes by a different symptom, yet loss of the knee-jerk alone enabled me to speak with certainty as to the nature of the disease. The patient was fifty-six years of age, married, and father of two children, and had been actively engaged in business; his chief complaint was of great depression of spirits, indigestion, and tightness round the chest, which he had had for about two years. A feeling of constriction of the chest being a common symptom of tabes, I examined the patellar tendon-reflexes, and, finding them completely absent, had no difficulty in eliciting the history and presence of numerous other symptoms of that disease. It appeared that the patient had had syphilis ten years ago. Eight years afterwards he began to complain of numbness in the third and fourth fingers of both hands, of dull pain in the back and legs, of incontinence

Digitized by Google

of urine, constipation of the bowels, and loss of sexual desire and power. In addition to these symptoms, there was now reflectory rigidity of the pupil's, Romberg's sign, difficulty in going downstairs, a sensation as if there were a pad of india-rubber under the soles of the feet, and slight ataxy in walking.

In December, 1881, I was consulted by an officer, aged thirty-seven, who had served fourteen years in India, and had suffered there during the whole of that time, more or less, from congestion of the liver and diarrhœa. He contracted syphilis in 1872, and had afterwards specific eruptions, chiefly on the legs, sore-throat, and persistent soreness of the tongue. His chief complaint, however, was of sleeplessness, which had come on sixteen months ago, and proved most obstinate, as it resisted all the remedies usually given for that condition. A feeling of general prostration, which he had had since that time, was by the patient attributed to the loss of sleep. Another symptom he mentioned was a feeling of "fierce compression" round the chest, and this led me particularly to examine the patellar reflexes. Finding them lost, I looked for other symptoms of tabes, and found great flabbiness and emaciation of the muscles of the legs, motor debility, numbness in all four extremities, and great diminution of sexual desire and power.

There is reason to believe that loss of the knee-jerk is in some cases the first, and in the majority of cases one of the first, symptoms of tabes spinalis. The diagnostic importance of this phenomenon, and of the modifications which it undergoes in certain cerebral and spinal diseases, is now almost universally acknowledged; and it is not too much to say that we owe a debt of gratitude to the distinguished physician and teacher who first drew our attention to it, for the new light which the study of this symptom and its modifications has thrown upon many obscure conditions of the nervous system. It seems singular that even now this symptom is very little thought of in France. Vulpian, in his otherwise very able lectures on diseases of the nervous system, makes a sneering remark about the discovery "which Westphal thinks he has made;" and Fournier laments the uncertainty which attaches to the diagnosis of the early stages of tabes, when such a symptom as this is within his reach.

It is not necessary for me to allude in this place to the different theories which have been started concerning the causation of the knee-jerk, nor to the diseases of the motor sphere in which it may be lost, such as infantile paralysis, pseudo-hypertrophy of the muscles, and atrophy from neuritis, such as occurs after diphtheria, &c. I will only add that in order to be pathognomonic for tabes, Westphal's symptoms must be combined with good voluntary power, a proper faradaic response, and idio-muscular contraction of the quadriceps femoris in response to direct percussion.

While, therefore, *loss* of the knee-jerk habitually indicates tabes spinalis, even where other symptoms seem to point in a different direction, its *presence* or *exaggeration* will show us that, although many symptoms of tabes may be present, yet the case is not one of locomotor ataxy or sclerosis of the posterior columns of the cord, as generally understood. In such cases, which are far from uncommon, we have rather to do with a combined system—disease of the posterior and lateral columns, or with insular disseminated sclerosis, than with tabes spinalis. The exaggeration of the knee-jerk is then to be explained by the sclerotic irritation of the lateral columns, which is too powerful in its effects to be neutralised by the disease of the posterior columns. Lightning pains are mostly absent, and the difficulty in walking is rather owing to paresis than to ataxy, or to a combination of these two conditions.

In February, 1883, a miller, aged thirty-one, married, and father of two children, was admitted into the hospital under my care. He denied any syphilitic infection, and attributed his illness to the severe chills which he had habitually experienced in his business. Twelve years ago he had broken his right leg, and there was now a large exostosis on the tibia, which but for this history might have been looked upon as one of a syphilitic character. His present illness commenced three years ago, when he lost his taste and had double vision. At the same time he found that he could not walk so well as before, more especially in the dark. After a time the sense of taste gradually came back, and he saw things single again; and two months after having first been taken ill the power in the legs improved so much that he thought he walked as well as ever. Twelve months ago, however, he began to get worse again, and the disease has since then gradually gained upon him. On examination the brain and cranial nerves appeared to be healthy. The patient complained of a sensation as if he had a tight rope round his chest, of difficulty in retaining the urine, obstinate constipation, and complete loss of sexual power. He felt numbness in the hands, and had some degree of ataxy in the upper extremities, more especially when he attempted to write. His gait appeared to be a mixture of ataxy and paresis, as there was decided loss of muscular force together with jerkiness; the patient had to manœuvre with his arms while walking, as otherwise he felt too unsteady to go on; and on shutting his eyes he staggered to such an extent that he would have fallen unless supported. He also complained of numbness in the soles of his feet; but he had never had lightning pains or any other kind of pain. On testing the deep reflexes, I found them all very much exaggerated, and I therefore concluded that the case was not one of tabes spinalis, but one of an unusual form of insular sclerosis of the spinal cord, which had affected several strands of fibres in that organ, but had spared those which are more particularly concerned with the sensation of pain, and deep reflex action in the posterior columns. The absence of lightning pains is, however, not invariable in such cases, as shown by the instance of an Irish farmer, aged fifty-one, married, and father of two children, who consulted me in October, 1882. He complained of incontinence of urine, loss of sexual power, obstinate constipation of the bowels, inability to walk in the dark, numbness, and occasional attacks of lightning pains in the legs, the muscles of which were thin and flabby, and several other symptoms. He had had syphilis badly ten years ago. The patellar reflexes were greatly exaggerated, and I therefore concluded the case to be one of a combined system-disease of the lateral and posterior columns.

A case in which there was a very marked combination of paresis and ataxy was that of an accountant, aged thirty-two, single, who was sent to me by Dr. Hausemann of Wildbad, in October, 1879. This patient had knocked about town a good deal ten years ago, and had then had a chancre which was followed by a large crop of secondaries, chiefly on the skin and in the throat. Two years afterwards he had repeated attacks of neuralgia and aphasia, and was inefficiently treated in Java, the Cape, St. Helena, and various other places. He was better and worse off and on, but about three years ago began to suffer from more definite symptoms of spinal disease. He had now the greatest difficulty in getting up from a chair, in standing and walking. There was great loss of muscular force, more particularly in the right leg. The bladder was so irritable that he had constant desire to micturate, and there was incontinence during sleep. The bowels were obstinately constipated; the sexual power almost entirely gone. The knee-jerk was greatly exaggerated on both sides, and it was therefore evident that the case was one of combined system-disease of the cord. In this case likewise no lightning pains had occurred at any time.

Harley-street.

SOME OBSERVATIONS ON THE

SPINAL CORD IN HEALTH AND DISEASE AT THE REGION OF THE FOURTH AND FIFTH DORSAL VERTEBRÆ.

BY ALEXANDER HARKIN, M.D., F.R.C.S.,
CONSULTING PHYSICIAN TO THE MATER INFIRMORUM HOSPITAL, BELFAST.

IT may be safely affirmed that in these days of progressive medicine and scientific investigation the department of neurology is the most advanced and the most prolific in results, and that through the labours of its votaries in this country, on the Continent, and in America, our knowledge of the causes, the nature, and treatment of nervous disorders is being enriched by an almost daily increment of valuable discovery. Much, however, as neurological science owes to the specialist and to experimental research, it should not be forgotten that to clinical observation and correct symptomatology many important discoveries must be accredited. Marshall Hall in our own country, and Duchenne of Boulogne, whose original researches have made their names immortal, were not specialists in any sense of the

Digitized by Google

term; they were great clinical teachers and voluminous writers, who, whilst labouring in the wide field of general medicine, allowed no limits to be put to their thirst for scientific inquiry. The spinal cord and its envelopments have engaged the special attention of neurologists, and their diseases, whether functional or organic, have also supplied material for the gravest consideration; our knowledge of their intimate nature and causation has thus been commensurately advanced; and we may reasonably hope, through the classification and subdivisions of the spinal axis recently proposed by French and German *savants*, to attain to greater accuracy in the treatment and prognosis of this interesting class of disorders. Up till the time of Budge and Waller no attempt had been made to subdivide the spinal cord into pathological regions; these eminent physiologists, indeed, only mapped off the cervical and upper portions of the dorsal vertebræ, under the name of the centrum cilio-spinale, because they found that irritation of this region produced dilatation of the pupil, through the action of the cervical sympathetic upon the iris. It is, however, with a region of much smaller dimensions, but possibly of even greater importance, that we have to concern ourselves at present—viz., that portion of the dorsal cord covered and limited by the fourth and fifth dorsal vertebræ. For many years, and soon after my introduction into practice, I had invariably observed in every case of hysteria, chorea, neuralgia, facial paralysis, and other neuroses in females, the co-existence of pronounced spinal tenderness on pressure over the fourth or fifth, more frequently the fourth and fifth dorsal vertebræ; with this practical result, the almost invariable and rapid cure of those maladies by remedies applied over these vertebræ alone. At first I regarded these manifestations as attributable to the peculiarity of the female constitution, its sensitive nervous system, its proclivity to emotional influences, and its general structural excitability; but, soon after recognising a similar condition of the spinal column in males so affected, I perceived that it was not referable to the female habit of body alone, but to localised lesions of distinctive character common to either sex, which in the absence of a more technical nomenclature might be considered as a form of so-called "spinal irritation." Still further observation elicited the extraordinary fact that this local spinal peculiarity, which at first I had looked upon as a morbid symptom, and the heritage of enfeebled constitutions, was in reality the normal condition of every healthy individual as well, of every age and class.

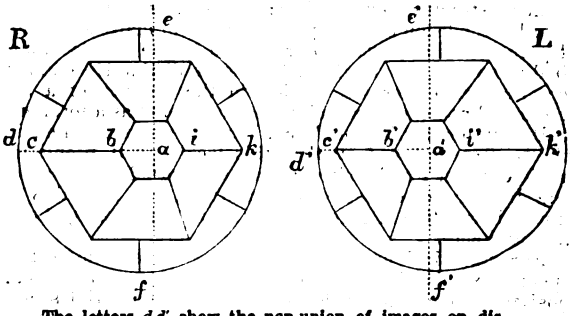
For statistical purposes some years since I instituted a special examination of healthy persons of various ages and positions in groups, such as inmates of industrial schools, reformatories, &c., and men in the public service, with the following result:—1. Of 131 female children and girls, from six to sixteen years of age, inmates of the Female Industrial School, Crumlin-road, Belfast, whose spinal columns I examined separately, and in the presence of the matron on May 16th, 1881, everyone complained of acute pain when tapped with the knuckles over the fourth or fifth dorsal spines, and a large number on the fourth and fifth; no pain being spoken of when the remaining twenty-two spinous processes were similarly treated. 2. Of thirty-five women of various ages confined in the penitentiary at Ballynafeigh, near Belfast, whose vertebral prominences I examined along with a medical friend on May 24th of the same year, whilst the greater number complained loudly when percussed over the fourth or fifth dorsal, a number resented the examination, were sulky, and gave indefinite answers. 3. Of thirty-one lads committed for crime to the Malone Reformatory, Belfast, whom I similarly examined on May 28th, 1881, separately and in the presence of their medical attendant, and whose ages ranged from eleven to nineteen years, each one yielded with a cry of pain when tested similarly over one or other of these processes; about one-half over the fourth, four over the fourth and fifth, and the remainder over the fifth alone. 4. Of 300 men between twenty-one and sixty-five years of age, members of the Royal Irish Constabulary, equal in physical development to any men in a regiment of the line, and under my professional care, whose vertebral columns I examined at various times, every man shrank with an expression of pain when similarly tapped over the fourth or fifth dorsal, the great majority over the fifth, some on the fourth and fifth, the remainder on the fourth only, and, like the other classes examined, exhibited no signs of pain or inconvenience when the remainder of the spinal column was similarly examined. Of the existence of this limited zone of spinal hyperæsthesia in the healthy subject, anyone may satisfy himself by tapping sharply over the dorsal spines of a friend, when the phenomena I have noted will at once become evident; or, if still doubtful, he can experience in his own person its reality, through the instrumentality of another; but the knuckles or the percussion hammer must be made to strike the spinous processes vertically and not at an obtuse angle, or in a careless or perfunctory manner, as otherwise disappointment is likely to result. The pain experienced over these sensitive points is peculiar; some compare it to an electric shock diffused over the chest and arms, others liken it to the tingling sensation caused by a knock upon the ulnar nerve at the bend of the elbow, and all declare that it is of a most disagreeable nature. It is evident that the constant presence in the healthy and the delicate constitution of this latent form of spinal hyperæsthesia must, to a great extent, affect the teaching of those writers upon spinal pathology who regard tenderness on pressure upon the vertebral column between the shoulders as a pathognomonic sign of spinal disorder. It had been for many years regarded as such by myself; but the fact of so many painful affections having been thoroughly cured by counter-irritation over this spot made the conclusion appear to me as absolutely certain; yet I was mistaken, for, paradoxical as it may appear, although counter-irritation in this place rapidly removed the complaint, yet when the raw surface healed up and the cure was complete, the original spinal tenderness remained as pronounced as at first.

Among the ailments which yielded so rapidly to the counter-irritant treatment were trigeminal neuralgia, facial paralysis (Bell's), acute hysteria, dysmenorrhœa, the reflex vomiting, the neuralgic toothache and the pruritus pudendi of pregnancy, gastralgia and other neuroses; and when vesication was the method adopted, I was generally able to assure the invalid that in five hours, coincident with the formation of the blister, all painful symptoms would permanently take their departure. By neuralgia I mean the typical disease of remittent character generally, but not always departing at night, to recur at the same hour every morning, or *vice versâ*, and not that hybrid ailment, principally rheumatic, so often miscalled; chorea has almost always yielded to this plan of treatment, with some important exceptions, including the chorea of pregnancy, and that form depending on organic cardiac disease. The dysmenorrhœa of neuralgic type yields readily, and I have not once failed for many years by a single vesication over these vertebræ to put an end at once to the sickness of pregnancy for the whole remaining period of gestation, no matter at what stage I was consulted. The neuralgic toothache, and the pruritus pudendi of the puerperal condition, yield as readily, and to one application.

In our present imperfect knowledge of spinal pathology, it is not easy to explain how it is that remedies applied solely to this limited area of the spinal column can control and cure disease located in the periphery and in distant organs. I have failed to obtain any proof that any fibrillary connexion can subsist between the dorsal cord or nerves and those conducting motor or sensory power to the organs under consideration. There is nothing peculiar in the structure or dimensions of the cord at the mid-dorsal region save that it is narrower and more compact than in other parts of the neural axis. The fourth dorsal spine, according to Gowers, corresponds to the origin of the sixth dorsal nerves, and the fifth to that of the seventh pair, and those are the nerves which might naturally suffer from the pain due to percussion on the corresponding spinous processes. But this, if true, would not remove the difficulty. While we are still unacquainted with many of the causes which excite or depress the sympathetic and its spinal centre, the controlling influence of this plan of treatment appears to confirm, to a certain extent, the teaching of Mr. Pridgin Teale, who believes that there exists an etiological relation between an irritable state of the spinal cord and sympathetic ganglia and neuralgic troubles in remote organs. Mr. Teale's propositions, however, only cover a portion of the subject, as, in his own words, "they refer chiefly to phenomena exhibited in those remote parts to which the nerves from the diseased portion (cord or sympathetic ganglia) are distributed." It does not explain the difficulty that counter-irritation of an area *unconnected* by nervous filaments with the seat of pain or paralysis will also as rapidly stifle the disorder. Being desirous of obtaining from a high authority a scientific explanation of the coexistence of this limited area of latent hyperæsthesia with neurotic disorder in distant organs, I wrote to Dr. Brown-Séquard in the summer of 1870,

Digitized by Google

requesting the favour of his opinion on the subject. I received a polite reply in August of the same year from Paris, just before the Prussians had closed in upon the doomed city. In that letter he says: "Why it is that some parts are more particularly attacked with vaso-motor spasm and others with vaso-motor paralysis we do not know, and therefore I cannot answer your question; but I can say that the morbid sensibility of the spine at the level of the fourth dorsal and of the seventh cervical is a sign of anæmia and hysteria, and that persons in health are free from it." At that time I was not myself cognisant of the fact that "persons in health" were as obnoxious to this "morbid sensibility of the spine at the level of the fourth dorsal" as the most neurotic sufferer. Why it is so I think it is needless to speculate. I fear it must be regarded as one of those conditions inherent in the human constitution which is beyond our power of elucidation; not so, however, when we inquire why counter-irritation upon a specified area of the human integument relieves pain or restores motor power in a distant part of the body. There is every reason to believe that, with due observation and well-directed experiment, a clear solution will be found, and already we may perhaps claim to have obtained an approximative explanation of the phenomenon. Treating on the subject of mechanical vibration for the relief of pain, Dr. W. J. Morton of New York says: "The general law which governs the relief of pain by counter-irritation has been recently formulated by Brown-Séquard, who, after careful experimentation, announced the general principle that general and local anæsthesia could be produced in the lower animals by applying to their peripheral nerve distribution a strong counter-irritant, like a few drops of chloroform, and that the anæsthesia was explicable on the theory of inhibitory action. A drop of chloroform on a guinea-pig's neck produced general anæsthesia. Here was an explanation of counter-irritant procedure in medicine. It requires little imagination to figure the time when a certain localised and known peripheral area of the human skin may be counter-irritated in order to produce an inhibition of pain in some spot far distant. At present the counter-irritation is applied as near as possible to the seat of pain. Undoubtedly many of the cures or reliefs of pain that are effected by general peripheral treatment, like slapping, rubbing, stroking with the hand, general applications of electricity, &c., are due to impressions on the fine peripheral network of the sensitive nerves, and conveyed to centres which set up inhibitory or relief responses, in their turn curative."[1] These suggestive words give perhaps the best available explanation of the pathological condition I have endeavoured to describe, and why "a certain localised and known peripheral area" of the human skin may be counter-irritated in order to produce an inhibition of pain in some spot far distant.



THE SECONDARY NATURE OF BINOCULAR RELIEF.

BY BRIGADE-SURGEON T. OUGHTON, A.M.D.

(*Concluded from page 14.*)

WITH a clear conception of the foregoing premises, the present hypothesis will be understood without much difficulty, and stands thus: Binocular relief is intrinsically the computation of a greater retinal image with a lesser correspondent retinal image, of a greater visual angle and its objective magnitude with a lesser visual angle and its objective magnitude; herein is comprised that compression which is essential to all relievo perceptions, whether tactile or visual. When the retinal images are precisely similar, we shall find that the image in one eye is under an extensor influence providing the image in the other eye is under a flexor influence, and these two influences will be of equal intensity; as a consequence, the object will be seen flat and without relief, being either coincident with the plane of the horopter (a plane at right angles to the median line of sight at the intersection of the optical axes), or with a plane that is parallel thereto. When the retinal image is greater than its fellow, the object will be seen in a concave relief relatively to the fixed binocular centre or horopter, providing the greater image is under an extensor influence; further, it will be seen as a convex relief relatively to the binocular centre when the larger image is under a flexor or approximating influence. In viewing the figures of the annexed diagram (the outlines of a direct bird's-eye view of a hexagonal monument standing on a circular pediment, drawn from two points of sight corresponding to the interocular distance), either in a stereoscope or by converging the eyes beyond the paper on which they are described, *R* will represent the delineation on the right retina and *L* that on the left. The most noteworthy facts are: First, that the pair of smaller hexagons are precisely similar, and the corresponding objective hexagon is a superficies that is coincident with the plane of the horopter; secondly, that the pediments are alike, and their corresponding objective is situated in a superficies beyond and parallel to the superficial hexagon; thirdly, that the pyramidal delineations are dissimilar, and are visible in an alto-relievo. In the stereoscope the delineations will be magnified, thereby proving that the extent of retinal area that is impressed does not affect the argument, which is as follows.

Converging the eyes on the points aa', so that the dotted lines ef and $e'f'$ shall indicate meridional lines of the retinæ, the larger segment, edf, of the right internal retina has to be accommodated to the smaller segment, $e'd'f'$, of the left external retina; hence the proximate causation of apparent relief. Every point in the segment edf is under an extensor influence, and every point in the segment $e'd'f'$ under a flexor influence. These opposite influences are equal in respect of the equal dotted lines ab and $a'b'$, and also of the equal dotted lines dc and $d'c'$; wherefore, extending a similar argument to both sides, the smaller hexagon and the pediment will be superficial extensions in the binocular resultant. The magnitude cb is greater than the magnitude $c'b'$—that is, the extensor traction on the right retinal delineation pre-

The letters dd' show the non-union of images on dissimilar lines of retinal latitude, and ee' the non-union of images to right and left of the retinal meridians.

ponderates over the flexor or approximating traction on the left retinal delineation; wherefore, the binocular resultant of the unequal and opposite magnitudes, $cb + c'b'$, will be a linear relievo, whose points, $c + c'$, will occupy a plane more remote than that of the fixed point, $a + a'$. A similar train of argument will, of course, be applicable to the right side of the apparent pyramid—namely, the extensor influence is to the flexor influence as the magnitude $i'k'$ is to the magnitude ik. If, in the next place, the diagram *R* represents the delineation on the left retina, and diagram *L* that on the right, the preponderating influence of magnitude cb over magnitude $c'b'$ will now be of a flexor nature; consequently, the points cc' will be approximated so as to occupy a plane nearer than that of the fixed points aa', and the pyramid will appear in sub-relief with the pediment in the foreground. This result may be effected either by transposing the above diagrams for the stereoscope, or by coalescing them by a process of strabismus; the latter is found to be a painful and impracticable procedure by many, but long-sighted persons usually adopt it. It is said that the binocular resultant is a beautiful miniature relief posed in mid-air between the observer and the plane of the paper—that is, at the site of binocular convergence. Brewster's theory of visual relief, it may be noted, explains the apparent position of the points on which the optical axes converge in this case, but it fails to account either for the apparent position of the entire miniature relievo or for the miniature creation.

It must be clearly defined what is meant by the term "retinal delineation" in the above argument; certainly it cannot mean the actual images on the retinæ, because the centre of the retinal curvature is acknowledged to be non-

[1] Transactions of the American Neurological Association, July, 1882, p. 57.

Digitized by Google

coincident with the centre of visible direction. The complications which have resulted from the want of coincidence between these centres in all diagrammatic attempts to explain the facts of binocular relief have been very perplexing; but the doctrine of secondary perception, as I have attempted to elucidate it, does not regard the actual perspective portrayed on the retina in any material degree whatever. The delineations really referred to are such as would be represented on an imaginary retina that is described about the centre of visible direction; they are supposed to be depicted on sensorial retinæ marking the path which any minimum visibile would traverse during rotations of the eyeball, by which the present subject is considerably simplified. Further, by no other means can the magnitude of a given visual angle be adequately expressed by the equivalent magnitude of a retinal delineation. It will be good practice, on the above principles, to solve the monumental relievo appearance on the datum that the eyes are converging on the remote points, *d d'*, of the diagram.

One prominent fact touching binocular reliefvo is that it rapidly diminishes with the distance of the object; thus a sphere will be perceived as a disc at the distance of forty or fifty feet. The present hypothesis covers it in this manner: as the object recedes to a greater distance, its delineations become more similar, the forces of flexion and extension become more equalised, until a disc is ultimately perceived with two precisely similar perspective impressions—for example, in the diagram, let the objective outlines of the pyramid be rendered more similar by increasing the interval between the smaller hexagons, stereoscopy will present a pyramid with diminished relief; so, an actual objective pyramid is seen with diminished relief at a distance, and for a like reason—namely, as it recedes the extensor influence, *c b*, of the right retinal delineation becomes lessened, whilst the flexor influence, *c' b'*, is augmented in an equal ratio; in other words, the balance of muscular influences operating on the resultant point, *c+c'*, is in favour of approximation. Conversely, let the outlines of the pyramid be rendered more dissimilar by approximating the smaller hexagons, *c b* (extensor force) will be greater, and *c' b'* (flexor force) less than formerly; but such outlines are the perspectives of an actual pyramid at a nearer distance, and seen with a more pronounced relievo. It will be unnecessary to deal with concave reliefs at a greater and less distance, since a like line of reasoning will be obviously applicable to their treatment.

Two or three exceptional facts cannot be disregarded with due justice to this subject. If, in the first place, the stereoscopic perspectives of a human face be transposed, the features will be found to retain their natural positions, as viewed in a stereoscope, instead of appearing as a concave mask. This is one of those stunning perversions of sense which occasionally baffle the ingenuity of mental physicists, and suggest unsatisfactory explanations, relegating such phenomena to the instigation and unintelligible vagaries of a dominant *mens conscia*. But the contradiction is an apparent one, merely evidencing that the factors of binocular relievo are eclipsed by another force of positional proximity—viz., the visual angle. Perceptions of visual angles are a monocular faculty; visual angles are the basis of perspectives and monocular relief, and different perspective magnitudes are the bases of the binocular reliefs under consideration; if, therefore, any relief that might have been forecast by the mind (the hollow mask in the present instance) be found to deceive the natural expectation, the only warrantable conclusion will be that some irregularity exists in connexion with the perspective arrangement or foundational visual angle. Granting that the hollow mask be visible in the binocular resultant, the nose with a greater visual angle than the more distant ears would be actually perceived further away, and it would intervene between and occlude objective points which an actual hollow mask would present to view. The entire circumstances of this exceptional fact are unnatural, since no binocular camera could produce a pair of facial representations transposed as above; hence I feel justified in regarding it as an instance of monocular relief, inasmuch as binocular coalescence cannot be maintained here any more than in the attempt to unite diagonal lines crossed in different directions on each half of a stereoscopic slide (experiment of Helmholtz).

Next, objective magnitudes in the plane of the horopter do not subtend angles to both eyes sufficiently equal for plane vision, or effect sufficiently similar retinal delineations within a less distance than eighteen inches from the observer.[1] Let two semicircles be described, with an interval of 2·5 in. (interocular distance), representing the sensorial retinæ above defined; then, subdividing them into an equal number of arcs (so-called corresponding points), let lines be drawn through the centres of visible direction. It will be found that corresponding pairs of lines intersect each other about Müller's horopteric circle when the point of optical convergence is three or more inches distant, the circles enlarging with increase of distance. Why are visible points stationed in such horopteric circles seen in their true positions, and not in the plane of the horopter? Again, if a magnitude in the plane of the horopter, distant about eight or ten inches, be divided into a right and left half, it will be found that each half subtends a larger visual angle to the eye on the same side than to the opposite one—clearly a result of foreshortening; in other words, the extensor influence on such a magnitude will preponderate over the flexor influence, so that it should be seen binocularly as a sphere with a convex relief. This fact seems to have reference to an interesting experiment recently published by Le Conte Stevens of New York. He constructs a pair of perfectly similar figures, each consisting of a series of concentric circles, and combines their images by crossing the optical axes; the result is said to be the appearance of a miniature buckler convex towards the observer.[2] But, whether there be a relation or no, an analogous foreshortening exists in a picture at a distance of ten inches. How is it that the objects of the picture are not perceived about a curved plane having its convexity towards the observer? Both the above questions are related to the same causative fact, and clearly demonstrate that the principles enunciated herein do not apply to objects within a distance of at least a dozen inches. The discrepancy is resolved by regarding the visual positions of such very near objects as equalling tactile position in definition, and as coinciding mathematically with the intersection of their lines of visible direction—that is, the forces influencing relievo are in abeyance to positional forces determining a directive composition, as in the case of an object at the binocular centre.

Lastly, the remarkable panoramic painting of "Tel-el-Kebir" by M. Philippoteaux *fils* (now exhibited at the Crystal Palace at Sydenham) presents reliefs of objects near and far, of horizon and sky, that are facsimiles of nature, notwithstanding the delineation is limited to a plane canvas that is only forty-five feet equidistant on all sides from the spectator. This variety of binocular relief forms part of another subject, which cannot be discussed at present; however, it is inconsistent both with the present hypothesis and with the law of visual position coinciding with the intersection of corresponding lines of visible direction. It must be understood that the present remarks are limited to relief within a distance of some fourteen or fifteen yards only—that is, the area of most useful vision.

Forest-hill, S.E.

TWO INSTANCES OF REMARKABLE ELEVATION OF TEMPERATURE.

By LAWSON TAIT, F.R.C.S. Edin.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

The remarkable case of elevation of temperature recorded by Mr. Teale, of Scarborough, in the Transactions of the Clinical Society is almost paralleled by the instances which I desire now to put on record.

The first case was one of removal of both ovaries for very rapidly growing cystoma, in the treatment of which I was associated with Mr. Chavasse of Wylde-green, and Dr. Thomson of Kingswinford. The operation was performed on Dec. 23rd, 1879, and presented no special difficulty, save that the tumours were of large size and practically solid. The following are the records of interest, and I may say that they were made by a competent nurse, verified by myself,

1. The images of said magnitudes will be mathematically dissimilar at a greater distance than that stated, but such dissimilarity is too fine for visual recognition. Strict mathematical rules are, in fact, inapplicable to the phenomena of apparent relief as well as to other visual conditions. For example, were vision controlled by the mechanics of rigid mathematics, one would be able to halve a given straight line definitely at a single glance without resort to artificial admeasurement. And, further, a given relievo object would present an unmodified appearance of relief at any and every distance.

During the night of the 25th no observations were made, as the patient was in a deep sleep, and it was not deemed advisable to wake her. Throughout the twelve hours during which the extreme rise of temperature lasted the patient experienced no uneasiness, and nothing was done specially for her condition—that is, no ice-collar or ice-cap was used. She made an excellent recovery, and has since married. She has had perfect health since her convalescence.

The second case was sent to me from South Africa, clearly suffering from chronic ovaritis. She was a hospital nurse during the Basuto war, and is a well-educated and intelligent woman, who can give an extremely clear account of her own case. Whilst lifting a heavy wounded soldier she hurt herself internally, and was immediately taken ill, the symptoms following being those of pelvic peritonitis. She was acutely ill from May 20th, 1882, till June 5th. The record of temperature observations was made by Dr. Jameson of Kimberley and Dr. Harrhy of Barkly, and four different thermometers were used. These statements are made by the patient. I have written to the gentlemen named, but have had one letter returned through the dead-letter office, and have got no reply to the other. The patient came to me in August last with enlarged and excessively tender masses on each side of the uterus. Perfect rest and treatment by counter-irritation and bromide have relieved her symptoms completely so far, and she is about to return to her duties.

* Cold pack.

From June 3rd the temperature rose from 99° in the morning to 100° in the evening, and in that condition I found it. This extraordinary record, of course, suggests, first of all, that it has been manufactured by a hysterical person possessed of sufficient education to enable her to forge. But the patient is not hysterical, and had abundant physical evidence of serious pelvic mischief when I first saw her. I admitted her to a private home, and had her carefully watched, and found no reason whatever to believe that she was endeavouring to deceive by presenting a manufactured register. My chief aim is that by its publication it may reach the notice either of Dr. Jameson or Dr. Harrhy, who may be able to throw some light upon it.

Postscript.—Since the above was written the patient has had relapses, and is now not so well. She has not yet gone back to her work, and I fear removal of the uterine appendages is looming for her in the future.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nullaautem estalia pro certo nosse adivia, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriis collectas habere, et inter se comparare.—MORGAGNI, *De Sed. et Caus. Morb.*, lib. iv. Procemium.

GENERAL LYING-IN HOSPITAL, YORK ROAD.

GESTATION; ACCIDENTAL HÆMORRHAGE; DEATH OF FŒTUS IN UTERO; ARRESTED LABOUR FROM RIGOR MORTIS OF FŒTUS.

FOR the following notes we are indebted to Dr. Robert Boxall, house physician:—

The following case of accidental hæmorrhage, resulting in the death of the fœtus in utero, presents the somewhat novel feature of arrested labour from rigor mortis of the child, and consequent inability of the head to undergo its normal movements in the pelvis.

Mrs. S——, aged twenty-nine, a fairly-nourished, healthy woman, of medium complexion and rather short stature, was admitted to the hospital at the full time of her sixth pregnancy, on Oct. 17th, 1883, at 8 A.M. She had always enjoyed excellent health. Her previous labours had been natural and easy. The external pelvic measurements were: Interspinous, 10 in.; intercristal, 11¼ in.; conjugate, 7¼ in. The patient had been under observation twice before, the first occasion being on Oct. 4th, when she complained of abdominal pains. The os was very patulous, and it was thought possible that labour was commencing; she returned home the same evening. The second occasion was three days later, when pain in the back was complained of. The condition of the cervix was unaltered; she stayed in the hospital some hours. At that time the fœtal heart sounds were distinctly audible. (It afterwards transpired that on each occasion, having had a "difference" with her husband, she sought the hospital as a harbour of refuge.) On reaching home on the evening of the 7th she noticed "a show," and from this time till admission suffered much from "whites," and experienced a sense of weight in the abdomen. She felt the child's movements up till the 15th, on which date they were stronger than usual, and "something seemed to go pop inside the womb." She remarked on this to the landlady. Immediately before experiencing this sensation she had carried a bucket of water up three flights of stairs. She felt a little faint, came over pale, and was obliged to lie down. After that she felt no more of the child, but had a pricking pain in the abdomen, which kept on continuously, and she could scarcely get about. From this time till admission she felt cold shivers, which she had never experienced with any of her previous children. Labour pains commenced about 5 A.M. on the day of admission. About 7 A.M., while still in bed, the pain in the abdomen and back was very bad, and suddenly without apparent cause flooding set in, and she lost "half a pailful," at any rate enough to soak through the bed and run in a pool on the floor. She came to the hospital, a distance of about a mile, in a cab.

When admitted, a thick diaper was soaked half through with blood, and there was still slight oozing. On examination, the os uteri was found high up, fairly firm, and a little puffiness of the anterior lip. The canal would admit the finger easily. The membranes were intact. The vertex could be felt above the brim in every direction. No part of the placenta could be reached. A pinkish sero-sanguineous discharge escaped in gushes at the commencement of each pain. The pains were strong and almost continuous. The patient was not strikingly pale. Temperature 98°; pulse 108. On palpating the abdomen the usual contour of the uterus was found to be maintained. No uterine sounds could be heard. The patient was douched every half hour, and given four ten-grain doses of chloral hydrate in an hour. As the cervix expanded the anterior fontanelle could be felt forwards and to the left, high up. At 12.30 P.M. the cervix was fully dilatable, and the membranes were ruptured artificially. The head, however, would not come down. The pains preserved the same character, and became a little stronger. As no progress was made, at 1.0 P.M. forceps were applied to the head. On the introduction of the lower blade about four ounces of liquor amnii escaped, and the head rotated

Digitized by Google

into the second position. The head was easily brought down through the cervix into the cavity, and as the pains then improved in character and remained of fair strength, with about a minute's interval between each, the forceps were removed, and nature left to take its course. The head was born at 1.45 P.M., a loop of pulseless cord following its expulsion. Though the pains were strong, the trunk was arrested. There was no attempt at restitution. With suprapubic pressure, and slight traction on the head, delivery was completed. There was no caput succedaneum. The child, a female weighing eight pounds and a quarter, and measuring twenty-two inches, was of a mottled blue colour, and stiff, as if rigor mortis had set in. This passed off in about an hour. The placenta followed the child into the vagina, and was expelled by natural efforts almost immediately after. About twelve ounces of recent clot was adherent to the uterine surface of the placenta. The portion of clot adjacent to the placenta was brownish, and detached without difficulty. The uterine surface of the placenta was a little gristy, and very smooth, yellow, and fatty-looking, from a thin lamina of fibrin covering its whole area. It also presented two yellowish fibrous masses, each about the size of an almond, near the centre, and another situated an inch from the edge, the size of a haricot bean. Nearly all the vessels on the fœtal surface were empty, and at the margin of the same surface were three pinkish laminated clots, not larger than almonds. The substance of all the cotyledons was softer in consistence than natural. The membranes, which formed an entire bag, measured fourteen and four inches respectively, in the greatest and least distance of their rupture to the margin of the placenta.

The temperature after labour was 98·4°; the pulse 72. The loss subsequent to expulsion of the placenta was almost nil. She had slight after-pains and retention of urine for the first twenty-four hours, but made a satisfactory recovery. Beyond a slight attack of urticaria, and a little pain in the breasts on the fourth and fifth days, the puerperium presented nothing calling for note. She left the hospital quite well on Oct. 30th.

CHESTER GENERAL INFIRMARY.

ABSCESS OF KIDNEY; ASPIRATION OF FORTY-TWO OUNCES OF PUS; COMPLETE RECOVERY.

(Under the care of Dr. DOBIE.)

FOR the following notes we are indebted to Dr. H. W. King, late house surgeon.

Arthur H——, aged thirty-six, a labourer, was admitted on January 4th, 1883. Upon inquiry the patient stated that his general health had been fairly good. Three months previously he caught cold from sitting on some damp grass. Soon afterwards he began to feel pain in his right side and back; he attributed this to rheumatism. Six weeks before admission the pain increased, and he was obliged to give up work. About this time he noticed a swelling in his right side; this had lately increased in size. He had been able to take very little food, had been feeling very weak, and suffered from night-sweats. His "water had been very thick" of late.

Upon examination a prominence was noticeable on the right side of the abdomen. Its point of highest projection was about one inch and a half from, and in a horizontal line with, the umbilicus; the skin over it was slightly pink in colour. There was a rounded swelling in the lumbar region, and laterally, continuous with the fulness in front. On percussion, absolute dulness existed in the right mammary line, and externally to it, from the upper border of the liver to the lower border of the tumour, about three inches above Poupart's ligament. Internal to this line there was a triangular patch of resonance (stomach), its apex outwards, between the liver and the tumour. Posteriorly dulness existed over the whole lumbar space. On palpation the tumour was movable, not adherent to the skin, and apparently not attached to the liver; but owing to the exhausted condition of the patient, the effects of forcible expiration could only be approximately judged. There was very evident fluctuation, especially where the tumour was most prominent. A thrill could be felt on percussion through the whole width of the tumour. Heart, lungs, and chest generally normal, but pulse weak (124), and breathing quick (28). Temperature ranged from 102° to 101·4° at night to 99·2° to 99·6° in the morning. Urine turbid, yellowish; after standing in a urine glass for two or three hours a yellowish deposit occurred of about half. Microscopically very numerous pus cells were seen, with some blood-corpuscles, renal epithelium, and amorphous urates. Dr. Dobie recommended that the tumour should be aspirated. On the afternoon of Jan. 10th forty-two ounces of thin but healthy-looking pus were removed by the aspirator in about an hour and a half. A needle corresponding in size to a No. 2 trocar was used. The patient at once felt much relieved, but had pain near the point of election for aspiration, which was in the centre of the prominence. Later in the evening the pain increased, and extended round to the back. The patient's legs were drawn up. One-third of a grain of morphia given subcutaneously relieved the pain and afforded sleep. The peritonitis continued for three or four days, and much consequent anxiety was felt as to the result. Opiates and hot fomentations relieved the pain, and the patient was able to take fair quantities of milk. The tumour diminished greatly in size, and dulness was now only present on the extreme right of the abdomen and in the lumbo-dorsal region. On Jan. 5th, the morning after the aspiration, there was much less pus present in the urine, but this very small amount gradually increased, until on Jan. 17th the deposit was about one-sixth. The patient, however, continued to improve in health and to get stronger. The urine continued to have a considerable deposit of pus—one-tenth to one-sixth. A lumbar incision was proposed, but the patient refused further treatment, and returned to his home near the seaside. He subsequently became completely restored to health, and was able to follow his usual employment. He was admitted into the infirmary early in May of the present year for an ulcer of the leg; and his urine, then examined, was found to be perfectly normal, and had not a trace of albumen. There was, however, still considerably greater dulness on the right lumbo-dorsal region than on the left. But the patient looked, and asserted that he felt, quite well.

NORWOOD COTTAGE HOSPITAL.

CASE OF OVARIOTOMY.

(Under the care of Dr. J. H. GALTON.)

J. W——, aged thirty-four, needlewoman. No family history of tumours. The patient had had good health. Menstruation had been regular except for the last two months, during which she has seen nothing. Four years ago she first noticed a lump in the right side, which gradually got larger. Her increase of size she attributed to sitting at her employment. She experienced no pain till April 11th, 1884, when she went for a long walk and had a "stitch" in the right side. From that time she had a good deal of pain about the middle of the right lumbar region.

On April 15th the abdomen measured forty inches and a half round the umbilicus, was dull all over the surface except below the ribs and in the flanks. She had a thin, anxious, ovarian look; tongue clean; pulse 74; bowels regular. The uterus was normal to sound and freely movable; the whole of the roof of the pelvis was filled in with an elastic-feeling mass.—April 24th, 11.30 A.M.: Pulse 98; temperature 97·8°. The ward having been duly prepared and heated to the temperature of 64° (at which it was kept for ten days after the operation), and chloroform having been administered by Dr. Brockwell with Jünker's apparatus, an incision was commenced in the median line one inch below the umbilicus, and continued downwards for four inches. One vessel was ligatured and a few others twisted (the incision, though in the median line, went through the rectus muscle). Bleeding having ceased, the peritoneum was divided to the length of the incision on a Hey's director; a small quantity of ascetic fluid escaped, and the tumour was tapped by Simpson's trocar. Eighteen pints and a half of clear fluid were removed. The cyst was drawn forwards with great difficulty, recent adhesion on the right lower portion being separated by the hand. Four separate cysts were tapped, the last containing very glairy fluid, which would not pass through the large trocar. At the posterior part of the tumour a good deal of solid growth much interfered with the withdrawal; the pedicle was transfixed, and, a twisted silk suture having broken in the second ligature, a second transfixion was made and a thick silk suture was passed through tied in two places and dropped in. A small quantity of fluid was sponged out, and no further could be expressed by pressure upon the abdominal

Digitized by Google

walls; four twisted silk sutures were passed (threaded on double needles) through the peritoneum and buttoned, one silver suture closing the superficial part of the wound below. Antiseptic dressings were applied, no spray being used during the operation. The operation took one hour and ten minutes. Ten drachms of chloroform were used. The weight of the solid removed was 3 lb. 1½ z. At 1 P.M. half a grain of morphia suppository was given; slight sickness, brought up some food. Pulse 74; temperature 96·8°. Ordered twenty minims of the sedative solution of opium every six hours. Urine to be drawn off every six hours. Ice also to be given. 6 P.M.: Pulse 88; temperature 96·8°. No pain, except slight in back. 12 P.M.: Pulse 88; temperature 99°; perspiring freely.—25th, 6 A.M.: Temperature 100°. 9.30 A.M.: Pulse 90; temperature 100°. No pain or sickness; has slept during the night at intervals. Ordered one tablespoonful of beef-tea every hour. 4.30 P.M.: Pulse 98; temperature 100·8°.—29th, 11 A.M.: Pulse 104; temperature 99·8°. Inclination to go to stool at 9.30 A.M.; passed four ounces of urine while at stool.—30th, 10 A.M.: Pulse 118; temperature 100·6°. To take milk thickened with arrowroot, and an ounce of champagne every two hours. Wound dressed beneath the green protective; small quantity of dirty-looking, ill-smelling discharge. The buttons inverted into the wound, which appeared closed except at the surface. Slight distension of abdomen, no pain on dressing; an enema of half a pint of gruel brought away about a quart of liquid motion; also passed water naturally. 4.30 P.M.: Pulse 108; temperature 100·2°. Has slept well for three hours; no jumping. 10 P.M.: Temperature 100·4°.

May 1st: Pulse 118; temperature 100·4°. Has a bad collapsed look. There is a swelling of the right upper corner of the wound. Removed all deep sutures; in only one a little pus followed. No tenderness. Ordered two drachms of brandy every two hours. 3 P.M.: Pulse 116; temperature 100·4°. Looks better. At 1 P.M. passed urine naturally. Sick at 9 P.M. 11 P.M.: Pulse 107; temperature 100·2°.—2nd: Pulse 112; temperature 99·6°. Bowels acted naturally, and passed urine.—4th: Pulse 108; temperature 100·2°. On dressing the wound found surface adhesion giving way, and a small quantity of pus oozed from the right upper suture opening. Removed strapping. No offensive smell. Dressed with carbolic lotion and lint pad on either side of wound, fixed with broad strapping. Ordered two ounces of port wine and fish. 10.30 P.M.: Temperature 99·2°.—7th: Pulse 88; temperature 98·4°. Bowels action frequent, passing gritty foul-smelling semi-liquid motion. Ordered one drachm of castor oil and fifteen minims of tincture of opium. 10 P.M.: Temperature 99·6°.—8th: Pulse 88; temperature 98·4°. The oil acted once; no diarrhœa since. Placed patient on her right side to relieve back. 10 P.M.: Temperature 99·2°.—9th: Pulse 84; temperature 98·2°. Bowels acted once naturally. About two inches of the superficial part of the wound remain. No discharge. Dressed with dry lint. Ordered middle diet, with two eggs; to continue the port wine. 10 P.M.: Temperature 98·8°.—11th: Wound entirely healed, and progress continued uninterruptedly.

Remarks.—The case is of interest as showing that our cottage hospitals are equal to the demands of the larger surgical operations, and much of the success was owing to the careful and devoted attention of the nursing staff. A great advantage over the same operation in the London hospitals consists in the steadiness of the assistance rendered by the surgical staff of the hospital and others (Drs. Miller, Hetley, and Messrs. Sidney Turner, Gandy, and Plimmer), which was more reliable than that of comparatively untried students. The superior purity of the air is also an advantage for the cottage hospitals. The rapid improvement of the case on the removal of the deep sutures on the seventh day is worthy of notice, as also the failure of buttons to retain their place on the sutures, thus interfering with the surface healing. The large quantity of urine passed during the early days after the operation is remarkable—viz: First day, forty-four ounces; second day, sixty-six ounces; third day, forty-eight ounces; fourth day, forty ounces.

AT the inquiry into the circumstances attending the death of Mrs. Cutler (widow of the late Edward Cutler, F.R.C.S., Surgeon to St. George's Hospital), who died from injuries she received by being thrown from her carriage on the 4th inst., the jury returned a verdict of "Accidental death."

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Retro ocular Neuritis. — Amblyopia. — Irido-choroiditis. — Proptosis with Gland Enlargement.

A MEETING of this Society was held on July 3rd, Mr. Jonathan Hutchinson, F.R.S., President, in the chair. The President's paper was decidedly interesting to general medicine, and elicited considerable discussion.

Mr. NETTLESHIP read a paper on some cases of Retro-ocular Neuritis, in which acute inflammation seemed to take place in some small part of the course of the optic nerve. They were characterised by failure of sight in one eye, often accompanied by neuralgic pain in the temple and orbit, and pain on moving the eye. The disc often became more or less atrophic in a few weeks; the result was variable from complete recovery to total blindness. Two illustrative cases were quoted, the first being that of a lady aged thirty-four, in whom an attack of central amblyopia in the right eye was associated with pain in and around the eyeball, and followed by pallor of the disc. The patient had previously suffered from sciatica, and several of her relations had had gout or arthritis. The second case was that of a man aged fifty, who had rapidly and completely lost the sight of his right eye, and who presented no sign of cerebral disease; there was no evidence of syphilis or gout, the only thing being that some time previously the patient had had diplopia from paresis of the right inferior rectus. The failure of sight was usually at its worst in three days, except in the most severe cases; recovery when complete usually required about six weeks. The pain, which was often circumorbital, began before the dimness of vision, and there was a sense of stiffness on moving the eye quickly. In the majority of cases examination of the field of vision revealed the existence of a central defect; sometimes the field was contracted, at others this sign was absent. Changes in the disc were by no means constant, even in the worst cases. The cases had to be distinguished from embolism of the central artery; from progressive atrophy where one disc was affected before the other and from uniocular neuritis due to disease of the corresponding lobe of the brain. The greatest difficulty would be to distinguish them from the rare cases where a single violent papillitis occurred with severe localised pain. In some of his cases the symptoms might be explained by a periostitis of the optic canal; in others the mischief could not have been so far back; in some a rheumatic origin seemed probable. The majority of the patients were between twenty-five and forty. At least five of the twenty-four had had syphilis, and there was a good probability of it in six others. In four cases the affected eye became permanently blind; in eight more or less damage was done; twelve (exactly half) recovered.—Mr. JONATHAN HUTCHINSON said that he had met with a case in a young lady in whom there was a marked arthritic history. The blindness completely passed away. It was probably a case of gouty disease of the optic nerve.—Dr. STEPHEN MACKENZIE asked whether any examination of the blood had been made. It was known that slight papillitis might occur in leukæmia, and was supposed to be due to thrombosis of the orbital veins; in these states of blood also a diffuse retinitis may arise. He had not met with any cases of the kind; they were not cases seen in medical practice. It must be confessed that Mr. Nettleship had not given a satisfactory explanation. In the cases following "fever" what was the length of time between the "fever" and the neuritis?—Dr. C. E. FITZGERALD briefly related a case of dimness of vision in the left eye in a young lady in whom very slight ophthalmoscopic changes were present. This first attack ended in complete recovery of sight, but was followed by a recurrence of the same symptoms in the same eye after some months. Somewhat later the right eye had become affected and with intense neuritis. Later still loss of power of the right leg and arm set in. Ultimately there was improvement in all respects; vision of the left eye became nearly normal though there still existed slight haziness of the disc. There was a history of old "rheumatic" affection, and Dr. Fitzgerald regarded the case as arthritic in nature.—Mr. NETTLESHIP, in reply, asked Mr. Hutchinson what degree of blindness existed in his case.—To this the PRESIDENT replied that the

Digitized by Google

patient was quite blind of one eye. There had been no severe pain and the patient remained free from visual affection until a threatening of the same thing began in the opposite eye.—Mr. NETTLESHIP said, with regard to the blood, nothing had been noticed wrong in their general appearance, though no special examination was made. In one case the neuritis set in within one month or six weeks after the "fever," which was either malarious or typhoid. At present it was but guesswork as to the nature of the disease. The cases were not all of the same nature. Periostitis of the optic foramen was probably present where the pain was intense and late ophthalmoscopic changes occurred. Small gummata on the nerve would explain all the symptoms.

Mr. LAWFORD read notes of a case of Central Amblyopia coincident with Peripheral Contraction of the Fields of Vision. The patient, a lad aged eighteen, noticed failure of vision about five weeks after a fall. He also had some general nervous symptoms, for which he was an in-patient at Guy's Hospital. The central scotomata, at first absolute for form, became, as recovery progressed, scotomata for colour only. Eventually perfect acuity of sight was attained, and the limits of the fields of vision became normal. The other nerve-symptoms also disappeared in the course of six months.

Mr. W. ADAMS FROST read a case of Sympathetic Ophthalmitis subsequent to the excision of the exciting eye. A man, aged twenty-five, was admitted into St. George's Hospital on November 3rd, 1883, for iritis of the right eye. There was no history of syphilis or rheumatism; and the patient traced the commencement of the affection to some hair entering the eye while he was clipping a horse a month before admission. There was conjunctival and ciliary injection, and on the inner side a few vessels encroached on the cornea. The lower half of the cornea was thickly studied with punctate opacities, and there were numerous posterior synechiæ. Tension was normal. A week later there was slight prominence of the ciliary region above, and an upward iridectomy was performed. The staphyloma increased in size, the eye became very painful, and the anterior chamber shallow. On Dec. 15th iridectomy downwards was attempted, but no iris was removed. The pain being severe, the eye was enucleated on Feb. 2nd, the left eye being then normal; but, five days later, slight conjunctival injection and punctate opacities on the cornea were noticed, but neither pain nor tenderness. Atropine, exclusion of light, and pilocarpine injections were used. On March 19th there was a *single fine* posterior synechia. The cornea was clear; V=⅔. The globe of the excised eye was bisected, and one-half was mounted in glycerine jelly. The other half was examined microscopically by Mr. Jennings Milles (the microscopical sections were shown at the last meeting). He reported that the ciliary staphyloma was formed by a nodule consisting of inflammatory cells closely packed. The sclerotic over this was much thinned. The iris was firmly adherent to the lens, and its parenchyma infiltrated with small round cells. The choroid was thickened in its whole extent, especially in the region of the papilla.—Mr. NETTLESHIP said that Pagenstecher had described a tubercular nodule of the iris, which seemed to have been set up by hairs passing through the corneal tissue; he inquired whether any hairs had been found in Mr. Adams Frost's case. This question was answered in the negative.

Mr. JONATHAN HUTCHINSON read notes and showed photographs of a Remarkable Case of Proptosis. The patient was a Hindoo gentleman, who came to him for extreme proptosis of the left eye, having not long before lost his right eye from a similar affection. The eye was extremely protruded, and mostly downwards; the lower lid was everted. The movements of the eye were not much interfered with, but there was a good deal of chemosis. The edge of the lacrymal gland, which was greatly enlarged, was felt on a level with the upper margin of the orbit. The upper lid hung loosely, but the lids could not be closed. The face was puffy, especially in the parotid region, and under the jaw. The other eye had been attacked in a precisely similar manner about three years previously, and after varying for two years had finally become so prominent that a few months before he came under observation the lacrymal gland had been removed, as also a firm lobulated mass which occupied the upper and outer part of the orbit, and turned out, on microscopical examination, to be composed of fibro-adipose tissue; suppurative inflammation set in after this operation, and the eye was lost. Within a few days of this time the hitherto healthy eye became protruded, which naturally greatly alarmed the patient. As in the case of the other eye, there had been variations in the degree of proptosis, and looking to the ill effects of operative interference in the other eye, it was decided to try the local application of ice. This was sedulously applied to the eye, to the forehead, and to the nape of the neck for a week without intermission; the patient at the same time took small doses of iodide of potassium. At the end of this time there was a decided improvement; the ice was, however, continued, and later on mercury was given in combination with the iodide. The result was that the patient was practically cured, and had since remained well. In reference to the nature of the case, it was pointed out that the enlargement of the lacrymal gland could not be regarded as in any way causal; it was coincident, but nothing more. There must have been some swelling of the fibrous or fatty contents of the orbit which caused the protrusion; whatever it was, it was capable of spontaneous diminution, it was prone to relapse, and was, as well as the enlargement of the various glandular structures, under the influence of iodide of potassium. Malignant disease could be negatived from the fact that there had been no recurrence in the eye first affected. The disease was analogous, he believed, to a group that had been described by Brodie, and more recently Mr. Morrant Baker, where there was a tendency to the formation of ill-defined, but more or less lobulated masses of fibro-fatty tissue in the region of the neck, but in none of the cases that he had seen was there proptosis or enlargement of the lacrymal gland, though he had in one case found enlargement of the parotid gland in association with fatty masses in the neck. Though the condition was remarkably local, it was not one of new growth, but rather of hypertrophic development, there being no tendency to general obesity. He suggested that one reason why glands of different function should be associated in the enlargement, was that the hypertrophy was due rather to increase of the connective tissue elements than of the gland structure itself. Exophthalmic goitre might possibly be a member of the same family, and he noted that some of the cases described by Mr. Morrant Baker were irritable even to the verge of insanity. In conclusion, he pointed out that these fatty outgrowths underwent great changes in connexion with the state of health of the patient, and that much benefit was often derived from a change of air.—Dr. STEPHEN MACKENZIE spoke of the relationship of the case to Graves' disease, in which the antecedent vascular disturbance was noteworthy, as was also palpitation and altered cardiac rhythm. In Graves' disease he had frequently found that the continuous application of cold to the neck was followed by great improvement. He asked whether there was any enlargement of the thyroid gland.—Mr. GEORGE WALKER spoke of the case of a woman with marked proptosis, in which compression of the carotid artery in the neck stopped the pulse in the arteria centralis retinæ. He concluded that aneurysmal dilatation of the artery in the cavernous sinus existed and led to venous engorgement of the orbit. He also said that the dilated "lymph vessels" on either side of the vessels could be seen. In reply to Dr. Brailey, he said the existence of a semi-translucent border was inferred to be dilated lymphatics.—Mr. EALES related the case of a man, aged forty, a glass-blower, of intemperate habits. The onset was by an acute attack of headache, associated with protrusion of both eyeballs. In this case there was also perceptible enlargement of the lacrymal glands; the left cheek was scorched, and the left eye most protruded. In glass-blowers and the like a hyperæmic optic disc was common.—Mr. JESSOP asked whether iodide of potassium diminished the size of the fibro-fatty growths.—Mr. BROCKMAN, of Madras, said that in India some cases of elephantiasis, which was common amongst Eurasians, might be associated with proptosis, and considerable improvement was effected by iodide of potassium and mercury. As a syphilitic taint was also present in many cases of elephantiasis, he could not say whether remedies acted against the elephantoid or the syphilitic element.—Mr. HUTCHINSON, in reply, urged that nationality had probably nothing to do with the disease, since it excited as much attention in India as at home. With regard to the fibro-fatty growths, he did not know whether iodide of potassium was of benefit or not, but change of air and abstinence certainly were. The dilatation of orbital veins spoken of by Mr. Walker was not mechanical in Mr. Hutchinson's opinion. No one would deny the existence of the vascular element in Graves' disease, and the want of power to control the temper with great excitability as met with in cases of the "Morrant Baker"

Digitized by Google

type, showed that there were remote features of family likeness amongst all the conditions of which mention had been made. In his case no enlargement of the thyroid gland existed, and the patient was not in the least excitable. It would be very interesting to come across cases of gland hypertrophy associated with fat hypertrophy, but such cases had not been observed by Mr. Morrant Baker. With regard to the iodide of potassium, this never exceeded fifteen-grain doses three times a day, and began with only three grains. Ice was the means of cure without doubt in the worst stage of the case, but later on, perhaps, the mercury acted in conjunction with the iodide.

ACADEMY OF MEDICINE IN IRELAND.

At a meeting of the Sub-section of Public Health on April 10th, Dr. CAMERON read a paper on Antiseptic Experiments in the Vaults of St. Michael's Church, Dublin, celebrated for their antiseptic properties. Bodies dry up in a desiccated mass, rather than decompose, when deposited in these vaults. The author placed an infusion of melon in Tyndall's tubes, and having submitted both to a high and prolonged temperature so as to sterilise the liquid, he placed a number of them in a vault of the church which seemed to possess the greatest antiseptic properties. The tubes were deposited with great caution, and in such a way as to occasion the least possible disturbance of the atmosphere. The extremities of the tubes were broken by means of hot forceps, and the vault was kept locked up for six weeks. They were then removed from the vaults. Seven of the tubes presented no change, but in the remaining five there was great turbidity owing to the development of mycelium, &c. In the case of the liquid kept in the unbroken tubes at the laboratory of the Royal College of Surgeons, no turbidity was noticed in their contents. On nipping the ends of the tubes of those kept in the laboratory and the sound ones brought from the mortuary vaults, turbidity set in in less than forty-eight hours. The author did not venture to draw any positive conclusion from these experiments, but their results seemed to show that the preservation of the liquid was due to the great freedom from dust which he noticed in the vaults. Franklin had found that in the higher Alps organic infusions remained for a long time freely exposed to the air without undergoing decomposition, a fact attributed to the freedom of the air at great altitudes from dust, which of course included germs of various kinds.—Dr. MORE MADDEN referred to the famous vaults near Palermo, where two miles of galleries were lined with the dead bodies of monks. The sides of the galleries and the dead bodies, which were in a state of desiccation, were coated with dust. Of the character of the dust he knew nothing, but the antiseptic properties of the galleries were ascribed to the peculiar dryness of the air, and also to the nature of the soil in which the galleries were excavated.—Several members having made some brief remarks, the PRESIDENT expressed the hope that Dr. Cameron would continue his experiments.

Dr. T. MORE MADDEN, having recently read a paper in another section of the Academy on certain Mental and Nervous Disorders, called attention to other aspects of the subject, offering further evidence of the general prevalence and increase of insanity in all classes, and more especially amongst women, in whom it is frequently traceable to cerebro-nervous disorders originating in reflex irritation from utero-ovarian causes. There were also general moral and social causes. The facility with which any person could be legally confined as a lunatic was indefensible, seeing that any two of the most inexperienced of the 24,000 practitioners on the Medical Register could virtually consign any man or woman to a lunatic asylum. That this power was liable to abuse, he illustrated by cases in his own experience. He therefore suggested that the power of signing certificates should be restricted to certain officially appointed medical inspectors of lunatics, and that in the case of alleged female lunatics one of the inspectors should be a physician with some experience of the special functional disorders, the reflex consequences of which may either stimulate or eventuate in insanity. The Lunacy Laws differed in England, Scotland, and Ireland; and the pauper lunatic asylums in England and Wales involved an expenditure of upwards of £1,000,000, while those in Ireland cost £200,000, according to last year's accounts. The reform of abuses and the improvement of curative treatment could be attained with diminished cost to the public. Let all the lunatic asylums become public property, and, placed under one central official administration in each country. The compensation of proprietors of private asylums would not be a serious consideration, considering the profits that would arise from continuing these institutions as first and second-class State asylums, and ultimately these profits would relieve the cost of the general public lunacy system. He suggested the abolition of the office of resident medical superintendent of public asylums, whose functions he would transfer to lay governors or masters, leaving the resident physician free to devote himself entirely to strictly professional functions, in which he would be assisted by a staff of extern or visiting medical officers. A large number of the chronic and harmless patients of the weak-minded or semi-imbecile class would be cared for with greater comfort to themselves and less cost to the public outside the walls of lunatic asylums. As an amendment of the laws relating to so-called criminal lunacy, he suggested the adoption of a law similar to the 64th Article of the French Penal Code, and the appointment of medical assessors in all trials in which the plea of insanity was advanced.—Dr. NEVILLE took considerable interest in lunacy since his first professional appointment as locum tenens in one of the large county asylums. The effect the diseases of the female genital organs might have in the causation of mental trouble was apt to be exaggerated by gynæcological specialists, and the question of lunacy was sometimes looked at through gynæcological spectacles. Where it was a case of one specialist attacking another he discounted a good deal of the criticism. He knew some of the gentlemen who gave attention to diseases of the mind to have studied the diseases as earnestly as specialists did in any other branch of medicine or surgery. The great trouble taken both in public and private asylums could not be excelled by any specialist. As to the increase in lunacy, it should be remembered that the causes of lunacy had greatly increased—e.g., the wear and tear of modern life. On the other hand, the struggle for existence made it the more necessary to get rid of the drones of society; and certainly lunatics, being of no use to themselves or their families, were drones in society, and their families would be anxious to put them under restraint. Nowadays medical education had advanced, and with it the diagnosis of insanity. Specialists in diseases of the mind would say there had been just as much improvement in the treatment of insanity as in obstetrics. Indeed, he saw a complaint made in connexion with the meeting of the British Medical Association in Bedford that there had been no advance made in obstetrics for several years. But he did not admit the truth of either allegation. On the contrary, he believed there had been an advance.—Dr. HENRY KENNEDY said he did not see why private asylums should not be continued. That abuses might exist would be allowed, but there were competent inspectors to visit private asylums and investigate their management. As to treatment, cod-liver oil had been found almost a specific where there was a tendency to insanity, indicated by such symptoms as restlessness and refusal of food on the part of persons advanced in life. In all those cases death almost invariably ensued from tubercular phthisis. Dr. More Madden was in some respects right regarding the stress he laid on uterine irritation.—Dr. MORE MADDEN thanked the Sub-section for the reception of his paper.

Reviews and Notices of Books.

Handbook of Geographical and Historical Pathology. By Dr. AUGUST HIRSCH, Professor of Medicine in the University of Berlin. Vol. I.: Acute Infective Diseases. Translated from the Second German Edition by CHARLES CREIGHTON, M.D. London: New Sydenham Society. 1883.

THE members of the New Sydenham Society should be grateful to their Council for wisely selecting so world-famous a treatise as this of Professor Hirsch to be added to their series, and for securing the services of one so competent to translate the work as Dr. Creighton; for the book is indeed a marvel of industry and erudition, and one which ought to be consulted by every writer on medicine. It is more

Digitized by Google

than twenty years since the author published the first edition, and he is now engaged upon the second, the first of the three volumes of which is here translated. In the long interval of time between these two editions there has been a remarkable development in literature and in the interest taken in epidemiology, which Professor Hirsch has himself done so much to further. It is gratifying to find him testifying to the value of the results effected in this direction by the publications of our own Health Department and the Epidemiological Society. In speaking of the growth of the subject matter of his work, he may well say that "some attempt to treat of Geographical and Historical Pathology anew was not merely justified, but even called for"; and in devoting himself to the task, we can well understand how "it has involved an entirely new treatment of the subject." To be sure, in these days the historico-geographical method is giving place to a mode of inquiry that goes to the root of etiology—we mean the search into the nature and properties of the virus of specific diseases, which now engages so much attention. But although this experimental method may have taught us much concerning the essential nature of disease and its propagation, it cannot replace the work done on the older plan, the comprehensiveness of which has thrown so vivid a light on the manner of diffusion of epidemic disease on a large scale.

The volume before us treats of the Acute Infective Diseases—viz., Influenza, Dengue, Sweating Sickness and Miliary Fever, Small-pox, Measles, Scarlet Fever, Yellow Fever, Asiatic Cholera, Plague, Typhus, Relapsing Fever and Bilious Typhoid, and Typhoid Fever; and concerning some of these we may advert to a few of the more notable facts presented. As examples of the exhaustive character of the work, it may be noted that the chapter on influenza contains references to the literature of epidemics dating from 1173 to 1878, and that the bibliographical references to the article on malarial fevers fill fifteen closely printed pages.

Influenza is eminently an epidemic disease—sometimes, as in 1837–58 and 1874–75, assuming pandemic proportions and spreading over a great part of the civilised world. Professor Hirsch finds no proof for the assertion that the epidemics are subject to periodical recurrence, or that they habitually travel from east to west, as many have held. He points out also how variable influenza is in the manner of its spread, in some epidemics large tracts of country being smitten almost simultaneously, in others the disease spreading but slowly. Having a geographical distribution over all parts of the globe, influenza appears to be uninfluenced by telluric conditions, by season, or by weather, and is thereby very different from epidemic bronchial catarrh. Although undoubtedly due to a specific virus, the disease is not transmitted by aerial infection, for it often spreads in directions opposite to that of the wind currents. It is interesting to learn that so long ago as 1836–37 this disease formed the subject of a "collective inquiry" by the Provincial Medical Association, the question being whether influenza were contagious or not. The replies were almost wholly in the negative. Few of the present members of the Association, which now exists under a wider name and with a much larger roll of members, can be aware that nearly fifty years ago the scheme, which is now being more ambitiously fostered, had its prototype in this inquiry.

From the widely prevalent and long-known influenza the author passes to the comparatively modern disease Dengue—a malady of the tropics, characterised by articular pain and swelling, fever, and cutaneous eruption; and although of brief duration, succeeded by marked debility and anæmia, very rarely leading to a fatal issue. In its sudden outbreaks over large districts it resembles influenza.

Next follows a chapter on the English Sweating Sickness, which carries us back to the battle of Bosworth Field, and with which Professor Hirsch inclines to believe must be allied the miliary fever recorded in many epidemics, especially in France, but also in Italy and Germany, up to the present day.

The chapter on Small-pox is one which will repay the most careful study. Its records reach back to the time of Rhazes in the tenth century, but so common a scourge was it that it would almost seem as if in pre-Jennerian times epidemics were considered too frequent to be noticed; at any rate, literature is not so full of them as might be expected. Very interesting is the evidence which goes to show that the starting-point of the disease was in India and Central Africa, and the manner in which with advancing "civilisation" it has been carried to islands and colonial dependencies. It did not reach Australia until 1838, and it has never yet appeared in Tasmania and New Zealand; and America owes its introduction to the European invasion. It appears to be especially prevalent in Peru, "notwithstanding," says Professor Hirsch, "that the natives appear to have been acquainted with the protective power of vaccine long before the advent of Jenner." Upon the value of vaccination, and the need for its thorough enforcement, Professor Hirsch speaks in no measured terms; and the testimony of one who has made himself so familiar with the ravages of the disease in times before this beneficent discovery was given to the world is not to be despised. He disbelieves in the notion of epidemic periodicity, the only factors necessary for an outbreak being in his opinion individual susceptibility and the introduction of the virus.

Measles appears to be very widely distributed; but Scarlet Fever, common in Europe, is rare in Africa and Asia, and is less frequently met with in epidemics than measles. Measles, again, prevails most in cold seasons; scarlet fever appears to be uninfluenced by climate, or season, or weather. The varying intensity in type of measles epidemics is, he thinks, largely due to the care, or rather the neglect, of the sick; but scarlet fever presents in itself various phases of malignity, increased, it may be, by insanitary surroundings.

The chapters on Malarial Diseases and Yellow Fever, diseases especially suitable for study from the geographical standpoint, are full of detail; but we must pass them by with the remark that Professor Hirsch notes that some forms of malarial disease seem to have disappeared, and that other new types, including "typho-malarial fever," first brought to notice in the American civil war, have made their appearance.

Asiatic Cholera is the next subject treated of, and a succinct account is given of the four great epidemics: that of 1817 to 1823, which reached the borders of Europe, but did not pass beyond them; that of 1836–37, which traversed the countries of Northern Europe, Denmark excepted, and was conveyed across the Atlantic from Ireland to Canada and the United States, thence spreading to Central America and across the Andes to the Pacific, whilst it also spread from North to South Europe; that of 1846 to 1863, which pursued much the same course and was marked by a remission in 1850–52; and that of 1865–75, in which also a remission occurred in 1869–70. There are regions left which cholera has never visited—as Australia, the Pacific islands, portions of the East and West Coasts of Africa, Central and Southern Africa, as well as parts of South and North America; in Europe, "Iceland, the Faroë Islands, the Hebrides, the Shetland and Orkney Isles, Lapland, and the Russian territory north of the sixty-fourth parallel"; and in Asia, Siberia and Kamtschatka. But here and there in countries which have been the seat of the disease, some regions have escaped wholly or partially—as in Switzerland, Baden, Wur-

Digitized by Google

temberg, some mountainous districts in the south-east of France, north of Scotland, and parts of Greece. The mode of spread, the tendency to follow the course of rivers, the relation of epidemics to the level of, or rather to the admixture of air with, the subsoil water, the nature of the cholera virus, and the indecisive results of experimental research (of course Koch's recent work is not included, for this volume was published in 1881), and the non-contagiousness of the disease, are amongst the many points treated of.

Next follows a full account of the Plague, which has appeared in all parts of Europe at different times, but has never extended in Africa beyond the northern countries; whilst Asia, Syria, Asia Minor, Armenia, Persia, and India have been the seats of epidemics in the present century. Climatic influences, and especially a low temperature, are favouring causes, but not to the extent formerly accepted; indeed, extremes of heat and cold appear mostly to "cause the extinction of the epidemic, or are little favourable to its breaking out."

The history of epidemics of Typhus, with the overwhelming evidence of their association with insanitary conditions, overcrowding, and famine; the association of similar conditions in the case of Relapsing Fever, and the highly contagious character of both these diseases; and the final chapter on Typhoid Fever—afford much room for comment did space permit. No summary will, however, suffice to indicate the wealth of material so laboriously collected and so skilfully arranged, and our readers must turn to the volume itself, which will well repay perusal.

Dr. Creighton has performed his part of the task in a highly commendable manner; and he has added to the obligations of English readers by compiling an excellent index to the volume.

The Evolution of Morbid Germs. By KENNETH W. MILLICAN, B.A., M.R.C.S. London: H. K. Lewis. 1883.

THIS essay, a contribution, as the title-page informs us, to transcendental pathology, comes opportunely to remind us of the bearings of modern research upon the nature of disease. For although the notion that one so-called specific disease may, under certain conditions, be transmuted into another is not wholly novel, yet it must be confessed that the tendency of pathological discovery to resolve such diseases into the effects of the action on the body of various parasitic microphytes has given fresh impulse to such speculations. Grant the existence of specific organic germs, and there is no escape from the application to them of the doctrine of evolution—the truth of which must rest upon the universality of its operation. It is to Mr. Millican's credit that he has applied the evolution hypothesis to the elucidation of certain unexplained facts of disease in a way that has not heretofore been attempted, and with a boldness which can only be admired. It may be true—there is certainly no *a priori* objection to the hypothesis—that many, if not all, diseases which have an origin external to the human organism have primarily sprung from some common ancestral type, and consequently that variations and resemblances are due to reversions or other modifications similar in kind to those seen in the animal world. It may be doubted whether such aberrations from the prevailing order are at all frequent, or that a really marked example of one specific disease could give rise to another of wholly different type. The existence of such hybrids as "rötheln," or of such gradual modifications in type as can be seen between tonsillitis and diphtheria, is suggestive of the truth which probably underlies Mr. Millican's contention. To establish it as true will require the accumulation of a large number of facts, and the work is one which we hope the author may be able to pursue

ST. THOMAS'S HOSPITAL MEDICAL COLLEGE

THE Archbishop of Canterbury presided at the distribution of prizes on Wednesday, July 9th. The following is a list of successful candidates:—

Summer Session.—First Year's Students—College prize £15 and certificate of honour: H. J. Smyth. College prize £10 and certificate of honour: S. B. Cook. Certificates of honour: H. J. Macevoy, S. W. Wheaton, H. A. Sansom. Second Year's Students—College prize £15 and certificate of honour: E. S. Gooddy. College prize £10 and certificate of honour: A. E. Godfrey. Certificate of honour: K. Totsuka. Third Year's Students—College prize £15 and certificate of honour: H. W. G. Mackenzie. College prize £10 and certificate of honour: R. T. Cann. Certificates of honour: J. R. Staddon, E. D. Ritchie, R. Lawson, F. C. H. Piggott, G. F. C. Williams.

Winter Session.—Entrance Science Scholarship—Scholarship £100 and certificate of honour: C. W. Cooke. Scholarship £60 and certificate of honour: F. Fawssett. First Year's Students—The Wm. Tite Scholarship £30 and certificate of honour: F. Fawssett. College prize £20 and certificate of honour: E. Webster. College prize £10 and certificate of honour: H. H. Heffernan. Certificates of honour: C. H. Eccles, R. V. Solly, W. W. Ord, C. W. Cooke. Second Year's Students—The Peacock Scholarship 40 guineas and certificate of honour: H. P. Hawkins. College prize £20 and certificate of honour: H. J. Smyth. College prize £10 and certificate of honour: E. Solly. Certificates of honour: H. Duncan, E. C. Stabb, E. H. Wright, S. W. Wheaton, S. B. Cook, J. H. Topking, H. P. Helsham, T. E. Stuart, W. F. Brook, L. A. Bidwell, H. A. Sansom, J. T. Calvert, C. T. Quiller. Third Year's Students—Second tenure of half the Musgrove Scholarship 20 guineas, with College prize £20 and certificate of honour: S. H. Jones. College prize £15 and certificate of honour: A. E. Godfrey. College prize £10 and certificate of honour, with second tenure of half the Musgrove Scholarship 20 guineas: K. Totsuka. Certificates of honour: J. S. Hutton, H. C. Kidd, A. A. Brockat, F. D. Crowdy. Anatomical Assistants—Certificates of honour: A. E. Godfrey, G. A. Macdonald, F. G. Parsons, K. Totsuka. Prosectors—Prizes and certificates of honour: H. Duncan, E. C. Stabb. Certificates of honour: L. A. Bidwell, A. B. Brockway, W. F. Brook, H. P. Hawkins. Resident Accoucheurs—Certificates of honour: F. F. Caiger, W. Fell, W. J. Sheppard, W. Wansbrough Jones. House-Surgeons and Assistant House-Surgeons—Certificates of honour: W. Wansbrough Jones, G. F. Cooper, F. F. Caiger, G. D. Johnston, W. J. Sheppard. House-Physicians and Assistant House-Physicians—Certificates of honour: A. Foxwell, H. Milton, C. D. Green, W. Hull, W. J. Sheppard, J. Orford, F. F. Caiger, W. B. Tomson. Solly medal and prize: J. Pietersen. Surgery and Surgical Anatomy—The Cheselden medal, founded by the late George Vaughan, Esq.: R. Lawson. Special mention and certificate of honour: R. Lake. Practical Medicine—The Mead medal, founded by Mr. and Mrs. Newman Smith: H. W. G. Mackenzie. Special mention and certificate of honour: H. Bidwell. For General Proficiency and Good Conduct—The Treasurer's gold medal: R. Lawson.

THE SUPERANNUATION QUESTION: A SAD CASE.

To the Editor of THE LANCET.

SIR,—There is now living in the village of Eastmeon, Petersfield Union, Hants, an ex-Poor-law medical officer by the name of George Pink, aged ninety years. He held the position of district medical officer in the Petersfield Union for more than forty years, and on his resignation, when upwards of eighty, applied for superannuation allowance, which was refused. I learn that he is now nearly penniless, and that if help be not afforded him he must go into the workhouse. I shall be pleased to receive any subscriptions that may be sent me in aid of this poor man, who under no circumstances can be a burden to anyone very much longer.

I am, Sir, yours obediently,

33, Soho-square, July 6th, 1884. JOSEPH ROGERS.

THE LANCET.

LONDON: SATURDAY, JULY 12, 1884.

THE election of Mr. COOPER FORSTER to the Presidency of the Royal College of Surgeons of England is not altogether of good omen, not because it fails to place at the head of the College an eminent surgeon, but because it perpetuates the evil and useless tradition of always electing the senior vice-president to the presidential chair. It further indicates that the Council still hesitates to bring the acts of the executive as far as practicable into harmony with the wishes of the whole of the body corporate. It will be remembered that one of the recommendations adopted at the general meeting of the Fellows and Members held at the College last March was to the effect that the President should be elected by the Fellows generally, and not exclusively by the Council as heretofore. It was argued that if it had been found necessary to have ordinary members of the Council elected by the Fellows, then *a fortiori* should the President be elected by the Fellows. The custom of always electing the senior Vice-President to the Presidency has, no doubt, often been attended by unexceptionable results, and has secured to the office many men distinguished not only as surgeons, but as administrators and medical politicians. On the other hand, it is notorious that adherence to this custom has, not unseldom, placed at the nominal head of the surgical profession of England some who were neither eminent as surgeons nor competent as administrators. Indeed, the accidental, uncertain, and indiscriminating character of the old plan of electing the President constituted its most conspicuous fault. Its other principal defect was that it excluded the specially ordained electoral body—namely, the Fellows—from participating in the particular election which most intimately concerns the dignity and prestige of the College. The antiquated system received its death-blow at the general meeting already referred to, and its doom has been definitely pronounced by the Association of Fellows, as well as by that of Members. The Council has, however, not the heart to give it the *coup de grâce*.

A fortnight ago such a resolute and decisive step would not have been expected. A majority of the Council as then constituted expressed its satisfaction with matters as they stood, and did not wish any alteration. A week might have effected more change. On the 3rd instant five members were elected into the Council, all of whom were more or less explicitly pledged to a programme of reform. It would have been an auspicious result of the first meeting if a departure had been taken from a mode of electing the President which has been condemned by many members of the Council and by the Associations of Fellows and of Members. The arrangements took their ordinary course last Thursday, and Mr. COOPER FORSTER, as senior Vice-President, was elected to the Presidency; and it cannot be denied that as far as his talents and services to the College are concerned this gentleman is as well qualified to discharge the duties of President as some of those to whom these duties have previously been entrusted. But many circumstances had conspired to suggest and justify a new departure. Exceptional circumstances call for exceptional measures. Impending legislation may affect the relations of the College, and it is desirable that the President at this time should be one who is not only acquainted with the affairs of the College, but who has a very strong hold upon the confidence and respect of the whole profession. The relations between the Council on the one hand and the Fellows and Members on the other are at present strained, and a wise and judicious man is needed at the head of the College to effect that compromise which can alone conciliate the disaffected at the same time that it perpetuates what is best in the traditions of the Council. A President who believes that the Council in all its dealings and relations is absolutely perfect, and who thinks that it is impossible to touch it without spoiling it, or an easy or indifferent President, who would be willing to perform his functions by deputy, might at this conjuncture curtail the influence and usefulness of the College, and even jeopardise its permanence. But, besides these weightier and more external considerations, there is a matter of domestic interest to be taken into account. On the 14th of next February the Hunterian Oration will be delivered. On the evening of that day the Council will entertain some of the most distinguished representatives of divinity, literature, art, and science, and it is desirable that the President of the College on such an occasion should exhibit the qualities of geniality, urbanity, grace, and culture. Without questioning the possession of these qualities by Mr. COOPER FORSTER, it cannot be gainsaid that no man in the profession is so richly endowed with these gifts as Sir JAMES PAGET. Consequently, we cannot avoid the conclusion that the election of Sir JAMES to the office of President for the ensuing year would have proved as popular as it would have been opportune.

KNOWING the sincere desire the Government entertain to pass their Medical Act Amendment Bill, and remembering how they have lost no opportunity of pressing it on, we write in the strong hope that it may be decided not to sacrifice a measure already so far advanced. Until Mr. GLADSTONE has uttered his fiat, however, we can write only on supposition. From the number and character of the amendments proposed there can be no doubt that in its progress through Committee of the House of Commons the Bill will be imperilled; and we must confess to entertaining grave anxiety as to the form in which it will be finally passed by the Legislature. Our readers will remember that although in the debate on the second reading of the Bill in the House of Commons there was a general consensus of opinion as to the necessity of the measure, and also as to the wisdom of its main provisions, there were yet numerous indications that many who supported the second reading only did so with the intention of introducing amendments in Committee. Of these the most important is that standing in the name of Sir LYON PLAYFAIR, which is as follows:—"The Medical Board in any part of the United Kingdom, with the approval of the Medical Council and the consent of the Privy Council, shall, in substitution for any final examination held in pursuance of a scheme or schemes under this section, accept the final examination in Medicine,

Digitized by Google

Surgery, and Midwifery, of any of the bodies hereafter in this section mentioned returning a member or members to the Medical Board—that is to say, of (1) any university; or (2) any combination of two or more medical corporations who may agree on a joint examination; or (3) any combination of a university with a university or universities, or of a university or universities with a medical corporation or corporations; provided (*a*) that the Medical Council shall be satisfied that any such substituted examination is equivalent in efficiency to the examination for which it is substituted; and (*b*) that in every substituted examination such number of examiners, not exceeding half the total number of examiners, as may be determined by the Medical Board, with the approval of the Medical Council and the consent of the Privy Council, shall be appointed by the Medical Board." If this amendment is introduced, the principle of a "one-portal" examination will be sacrificed, and those who have been hoping that at last an end was to be put to a system which is a disgrace to the profession and an injury to the public will be grievously disappointed. We may be sure that the corporations would at once enter into the necessary combinations, and that we should never see any independent and really trustworthy examination conducted by the Medical Boards. We have heard three arguments advanced in support of the amendment: that it is a hardship to compel medical students who have passed higher medical examinations to pass the easier one of the Medical Boards; that the expense of the two examinations will deter students from passing the voluntary higher examination; and that the double clinical examination will be too severe a strain upon the patients in the hospitals. How amused students must be when they hear such arguments advanced on their behalf! How can it possibly be a hardship upon a man who can pass a high examination to make him pass one of a lower standard in the same subjects! It could only be so if the higher were higher in name and not in essence—if it were concerned with the minutiæ and details while the great fundamental principles are neglected. We should be glad indeed if the argument of expense might be taken as showing that the corporations had any real regard for the student's pocket; but with the fact fresh in our recollection that the Royal Colleges of Physicians and Surgeons in London have entered into a scheme by which a diploma will only be given by either to those who have passed the examinations of both bodies, and who have paid the full fee now charged for each single diploma, we must refuse to regard this as anything more worthy than a pretext. All who are practically acquainted with the matter know full well that the clinical material available in London, Edinburgh, Dublin, and the other large towns where these examinations would be held, is abundantly sufficient, and that the double examination need not, and would not, inflict any injury, or even inconvenience, upon the patients in hospitals; this is but a false cry raised to win the support of those who, without personal and practical knowledge of the question, may be led astray by appeals to economy, or to their sympathy with suffering. But it may be urged, Are not the safeguards introduced into the amendment sufficient to ensure that this portal to the profession shall be satisfactorily guarded? We must answer with an emphatic "No." The universities and combined corporations would still be left free to compete to admit students to the Register, and all experience shows that where the spirit of competition can be allowed any scope in such a matter, it always tends in one direction only. So long as a student has a choice of several examinations before him, those who profit by his choice will be very sure to devise means of attracting him, and our past and present experience shows abundantly what these means are. The principle of the proposal is wrong; it perpetuates the very evil the whole Bill is intended to put an end to, and we doubt whether by any means it could be freed from ill results. It is impossible, too, to forget that this amendment is introduced in the interest of some of the existing examining bodies, and we may therefore be assured that they are fully alive to the ways in which they can turn it to their own advantage.

We trust that the Government may yet see their way to introduce a clause conferring a title upon all holders of the diploma granted by the Medical Boards. This is a matter to which we have repeatedly referred; the students, who of all people are perhaps most interested in it, have expressed their opinion in no uncertain way; it will injure no one, and it will make the necessary registrable qualification of real value to the holders of it. Without a title the holder of the diploma will labour under a serious disability, and two results may with certainty be anticipated—a renewal of agitation for fresh legislation on this point, and the use by the less scrupulous men of titles to which the examination they have passed gives them no claim. The Government should boldly grapple with the question, and we are confident that if they will fairly look into it they will see the justice and the necessity for granting some title with the registrable qualification, and we trust that at the same time they will reintroduce the clause referring to "higher titles" which was in the Bill as originally introduced in the House of Lords last year. They will thus close this question finally, and will earn the lasting gratitude of the profession.

PUBLIC opinion means well; but it is much mistaken in its policy in relation to baby-farming. A strong prejudice exists against the provision of any systematic help for the parents of children who are a burden either because they are illegitimate or because their mothers have to fulfil daily tasks of labour. It is easy to understand, and everyone must, as society is at present constituted, sympathise with, the anxiety to avoid offering "facilities"—such as are rightly or wrongly supposed to be offered in countries where foundling hospitals abound—for the rearing of children who are, so far as natural maternal care is concerned, abandoned. It is with difficulty that we maintain a single "Foundling Hospital" in London, and if the management of that solitary institution were not in trusted hands and known to stand on the highest moral ground, it would fail to secure even the very scanty consideration now bestowed upon it. A proposal to multiply foundling hospitals in this metropolis would be scouted as inadmissible on the score of moral policy. We do not, it must be confessed, share the fear of encouraging reckless living by the establishment of houses of succour for infants, though we comprehend and respect the feeling that begets that fear in other minds; but

Digitized by Google

we do stand in exceeding alarm at the indefinite perpetuation and extension of the evils that result from the refusal of the State to step in and provide the hospitals required. Whether we will or will not, there *must* be places and means of "taking charge" of children of tender age. Mothers *will* put their infants out to nurse, and if measures are not taken to provide places of safety for their reception, where the treatment they receive is under proper supervision, they will languish and die, in some instances, doubtless, to the grief, in others to the satisfaction, of their parents. Much misapprehension seems to prevail with regard to the significance of a full payment per week for the care of a young child. There is a disposition to accept the fact as evidence of good faith. We regret to feel compelled to look at the matter from another point of view. When a servant girl pays six shillings a week for the care of her infant, we fear it is generally understood—though not, perhaps, expressed in the agreement—that the number of weeks during which this heavy tax must be borne will not be many. The very liberality of the allowance shows that it is not meant to last. This is a point on which the Courts, as well as public opinion, probably stand in need of a little common-sense enlightenment. We only mention this as one of the facts about baby-farming which need to be scrutinised somewhat more closely than it is the wont to look into them.

It would be useless to license the keepers of baby-farms or to register these institutions unless they are to be properly inspected; and as secrecy in respect to the whole business is one of the first conditions on which parents insist, it is impossible, out of Utopia, to expect baby-farms to be conducted as private ventures without being misconducted. Sooner or later the State will have to make the provision required. Meanwhile, what is to be done? We have for many years past repeatedly pressed this matter on the attention of our readers, and, through them, on public opinion. It is a question of great importance. We have urged, and we again contend, that it should be made a misdemeanor to undertake the care of any child—not being the guardian's own child—whether for "gain" or for "love," without reporting the fact to the police. Even with this enactment there will be many cases of malpractice. Children will be represented as being the offspring of their custodians when they are in fact farmed; but a little vigilance on the part of the police will go far to render this form of imposture difficult. There might be a heavy penalty for misrepresentation. There should be no hardship in requiring those who take children in to nurse, on any terms, to notify the fact at the district police station. It would not be necessary or politic to require that they should give up the names of the persons by whom they were entrusted. This might be left a secret. No statesman would desire to throw needless obstacles in the way of the placing out of children to nurse. If it were not permissible to do this, and with a fair amount of ease, and perfect secrecy as regards the names of the parents, there would be a notable increase in the crime of infanticide. This must be distinctly borne in mind and provided against, or legislation, even on moral grounds, will be worse than useless. Again, the acceptance of children to nurse must be followed by the appointment of local inspectors, who should be empowered to visit the homes of persons known to have such infants in charge at proper intervals, and who should be held accountable for the supervision of these little ones as regards health and general management. Medical officers of districts under the Poor-law division of the Local Government Board would be suitable persons to perform this service, and while they are going their rounds among the poor, visiting the permanent sick, lunatics, and idiots, it would be easy for them to do the additional duty for the recompense of a small fee. Medical men are, of course, far better judges of "health" and "condition" as regards young children than constables or relieving officers can possibly be, and there would not be the same objection to the visits of a medical practitioner as to those of a constable or even a relieving officer.

It is clearly time that something were done in this matter. It is one of great urgency and gravity. We venture to think that even at this late period of the session a short Bill might be passed containing the three provisions we have specified. First, that all persons having the care of children not their own should notify the fact to the local police, or it might be notified by any other person by letter, addressed to the head constable or superintendent; second, that it shall be a misdemeanor carrying a heavy penalty to fail to make this notification, or to make any misrepresentation as to the facts; third, that the medical officers of districts shall be empowered and required to visit all places where children are farmed at short intervals—say once a month,—and to see and report upon the health and condition of the children so farmed. If the Legislature is practical and sincere in the often expressed wish to pass some satisfactory measure on the subject, this brief outline may be useful as a basis, and no real difficulty would, we believe, be found in framing and passing such a measure.

THE firmness of the hold which bacteria, and all that relates to them, have taken on the mind of scientific investigators may be accurately measured by the number and length of the contributions to periodical medical literature. A grand discovery, like a huge wave, is invariably followed by a succession of smaller undulations of varying size, which are of value in their own way. If complete reliance may be placed on the conclusions of M. PASTEUR'S recent work on Rabies, we may indeed congratulate scientific vivisection on having achieved a position which not only conclusively establishes its *raison d'être*, but ought surely to silence the unreasonable demands of the anti-vivisection movement.

The first communication to which we draw attention is one by OSOL on the virus of charbon, a disease which, though perhaps almost worked out, still continues to attract a large share of attention. Under the guidance of Prof. SEMMER of Dorpat, OSOL has studied the influence which the injection of charbon blood, deprived of its spores and bacilli by boiling, has on the animal organism. Blood taken from large-sized animals dead of charbon was first diluted with equal parts of water, boiled in glass vessels, and filtered while hot. The residue of the filtration and the coagulum formed by boiling were again treated with water, and once more boiled and filtered. After this double filtration the liquid was heated on three consecutive days for a period of two hours each time. Large injections were then made on rabbits and mice, with

Digitized by Google

properly cleaned syringes. Other animals used as control subjects were inoculated with minute quantities of the charbon virus. Some sterilised broth was also inoculated with some of the reduced virus, kept in an incubating stove. Finally, the blood of the sheep and horse, taken from healthy animals, was subjected to the same manipulations as the charbon blood, and then injected in the same doses as the latter into mice and rabbits. Animals inoculated with the charbon virus previously boiled have perished in from three to six days. Their blood and glandular organs, examined immediately after death, contained in a quarter of the number of cases the bacilli characteristic of splenic fever. In those instances where bacilli were not detected, innumerable micrococci like those described by MM. SEMMER and BOLLINGER in 1872 were found. According to these observers, the rods and cocci represent two complementary morphological elements. M. OSOL never came across the protococci recently described by M. ARCHANGELSKI ("Contribution à l'Etude du Contage Charbonneux." Dorpat, 1884). Inoculations with the blood from animals dead of the induced disease on sterilised culture liquids led to the development of typical forms of bacillus anthracis. The same blood syringed under the skin of rabbits and mice led to the death of this second batch, bacilli being also discovered in the blood and viscera. The control animals experimented on with minute doses of the poison exhibited no pathological manifestations. The sterilised liquids remained perfectly clear, thus proving that the boiled virus contained no living organisms. From these investigations, M. OSOL concludes that there exists in the blood of animals affected with charbon a specific virus, soluble in water, but non-volatile and of a chemical nature. When this virus is inoculated on animals, it modifies their liquids in such a manner that *indifferent* micro-organisms contained in the normal tissues are transformed under the influence of the virus into charbon bacilli at the end of from three to six days. M. OSOL does not underrate the importance of the bacilli, which he regards as the only agents capable of producing the specific chemical poison.

M. ZAHN has made fresh researches on the blood of rabbits, cats, sheep, and calves (VIRCHOW'S *Archiv*, p. 401, 1884), tending to prove that the blood of healthy animals does not contain the germs of putrefaction. He collected, with full precautions, small quantities of blood in tubes previously filled with hydrogen, oxygen, and carbonic acid, so as to exclude the atmospheric air. After weeks and months the contents of the hermetically sealed tubes, kept at a constant temperature of 37°-38° C., remained free from any sign of putrefaction.

M. HAUSER (*Centralblatt für die Med. Wissensch.*, No. 21, 1884) has searched for micro-organisms in living healthy tissues. Entire organs and parts of tissues, removed, by means of instruments previously heated, from animals just killed, were at once placed in super-heated glass vessels, the mouths of which were securely plugged with cotton-wool. These vessels were then kept in a moist chamber at a temperature of about 30° C. The conclusions arrived at by HAUSER were to the effect that micro-organisms do not exist in healthy tissues. The bearing of ZAHN'S and HAUSER'S experiments on those of M. OSOL are plain, since the last-named believes that healthy tissues do harbour germs.

BELTZOW (*Centralblatt für die Med. Wissensch.*, No. 21, 1884) has examined five cases of pyæmia and one of pyo-septicæmia, with a view to clearing up the nature of the germs associated with these diseases. He has found that the organs of human subjects dead of pyæmia contain, besides colonies of cocci, a considerable number of bacilli which belong to two distinct morphological varieties. One of these has a distinct resemblance to the bacilli of malignant œdema, and the others have dimensions intermediate between the bacilli of tuberculosis and the bacilli of the septicæmia of mice. In one case only, by the side of the cocci and bacilli, in the liver, colonies of leptothrix buccalis were discovered blocking the capillaries of the gland.

BAUMGARTEN has given the following method for the pure cultivation of the bacilli of tubercle. A tubercular nodule rich in bacilli, removed with due antiseptic precautions from a living animal or human cadaver, is transplanted into the anterior chamber of a rabbit's eye; as is well known, under these circumstances no inflammation follows. The transplanted nodule perceptibly augments in volume, and is allowed to do so for from eight to fourteen days. Microscopical examination shows that the increase in size is due chiefly to the germination of bacilli, and, at the same time, that the histological elements have undergone corresponding atrophy. If portions of this premier nodule be inserted into the anterior chamber of the eye of another rabbit, and so on for a series of rabbits, a time comes when an absolute pure culture of tubercular bacilli is obtained. The successive inoculations required by this procedure set up specific inflammatory lesions of the eyes, followed by generalised tuberculosis.

FALK has observed that putrefaction destroys the virulence of the tubercular virus. He has endeavoured to obtain by experimental means a benign tuberculosis by inoculating virus attenuated by putrefaction, at the same time hoping to discover a means of "vaccinating" against tuberculosis. Inoculation on rabbits with putrefying tubercular lesions was followed by a local tubercular mischief only, which ended either by suppuration or calcification, no internal lesions being discovered. But it was found that animals thus experimented on derived no immunity from fresh inoculations made with pure tubercle; indeed, tuberculosis seemed to ensue more rapidly.

BAUMGARTEN has fed rabbits with milk in which tubercle bacilli had been held in suspension. After a single meal of from fifty to forty grammes of this milk, the rabbits presented, with a remarkable constancy, tubercular infiltrations of the mucous coat of the intestine, mesenteric glands, and liver. The more charged the milk was with bacilli, the more extensive were the resulting lesions. In some of these latter cases the vermiform appendix and large intestine were eaten through with caseous ulcers, on the edge of which tubercles with epithelioid cells stuffed with KOCH'S bacilli were to be found. At the surface of the tonsils there also existed, in some cases, ulcerated lesions infiltrated with bacilli. BAUMGARTEN believes that infection takes place at the upper end of the digestive tract. Of other organs in these instances the lungs only exhibited tubercular lesions. This observer has also remarked that putrefaction lessens the virulence of the tubercular material.

LAST week an interesting and instructive lecture was delivered at the United Service Institution by Lieut.-Colonel

Digitized by Google

TULLOCH, C.B., of the Welsh Regiment (formerly the 69th) on the subject of Soldiers' Food. After a brief introduction, pointing out the sins of omission and commission, which until a recent period contributed largely to the very high rate of mortality which prevailed in our army, the author proceeded to consider in detail the various articles constituting a soldier's diet, under the headings of ration meat, bread, and groceries, and pointed out how much might be done for the benefit of soldiers by a little more supervision on the part of commanding officers and captains of companies. He then discussed the nutritive value of different foods and the amount necessary to keep a soldier in a state of efficiency. From a comparison of the nutritive value of the rations of foreign armies with our own, it appears that the total amount of water-free food in the Russian Army is 34·30 oz.; in the Prussian, 24·80; in the French, 24·14; in the Austrian, 23·30; and in the English, 23·13; so that our army stands at the bottom of the list as far as the nutritive value of the diet is concerned. Colonel TULLOCH then proceeded to offer suggestions as to the best mode of improving the existing rations; the management of the regimental canteen; the establishment of a recreation-room bar; and the introduction of a little more civilisation into the arrangements for the soldiers' meals in the barrack-room. The subject of food on troop ships was next brought under review, and the extremely difficult question of food on active service. On the latter point the lecturer pointed out the great difference which is observed in different regiments employed on the same service. "Some regiments will manage to keep well and send few men to hospital, whilst others precisely similarly situated, who are not properly looked after, suffer greatly. Instead of using strong language about the commissariat, who are often struggling against difficulties of which few but the General Staff have any idea, officers might often manage so as to add to the soldiers' rations," and he gave some instances of how this might be, and had been done. We think there cannot be a doubt that it would be most advantageous to add to the soldiers' food both in peace and in war, but the difficulty in the former consists in the large addition which it would make to the already heavy expense of our army; and in war, in obtaining supplies, and in providing and maintaining the great amount of transport necessary to keep up the commissariat with an army on the move. Lord WOLSELEY, in his "Soldiers' Pocket-Book," suggests the following as a liberal and varied war ration for British troops:—"Bread, 1¼ lb.; fresh meat, 1¼ lb.; peas or beans, 3 oz.; potatoes and green vegetables, 1 lb.; cheese, 2 oz.; sugar, 2 oz.; salt, ½ oz.; pepper, 2/16 oz.; ground coffee, 1 oz.; tea, ½ oz.; and wine, ½ pt.; or beer, 1 pt." On this recommendation Colonel TULLOCH justly remarked that "such feeding might be possible with a small force and a perfect system of transport; but a Commissary General who, anywhere but in India, could so supply a large army on the move would deserve a peerage." The paper was evidently carefully prepared, and was of an eminently practical character. The views of the author were well borne out in the discussion which followed, and especially by Dr. DE CHAUMONT, whose opinions on the necessity of feeding up our recruits and young soldiers met with general support. On one point only the paper seemed to be defective. The author made no reference to the hours at which soldiers have their food served out to them; and this is a matter in which a change is greatly needed. The long period of nineteen hours elapses between dinner and breakfast, the two principal meals of the day; and although it is true that the soldier has an evening meal provided, it is not of a very substantial character. It would, we think, be a great advantage if the hour for dinner were changed to four or five in the afternoon. We entertain a strong opinion that much of the drinking of our soldiers is due to a craving for something in the long interval, and that the thing most easily procured and most successful in allaying the feeling is found, or believed to be, some form of alcoholic stimulant. We trust that the subject of the soldiers' food may receive due consideration from the War Office authorities, and that steps may be taken to carry out the suggestions which Colonel TULLOCH has made with a view to an improvement in a matter having so important a bearing upon the health and efficiency of the army.

AT the annual meeting of the Royal Society for the Prevention of Cruelty to Animals, held on Monday last at St. James's Hall, Dr. RICHARDSON, F.R.S., had the satisfaction of reporting that one of the labours on which he has been engaged for a quarter of a century had been brought to a practical result of a most satisfactory kind to all friends of human progress. He observed, briefly, that he had been able to submit the inferior animals that have to be killed to a perfectly painless death under anæsthesia. In 1869 Dr. RICHARDSON proposed to the Society that such a plan should be instituted, and in 1871 he read a paper on the same subject to the Medical Society of London. The suggestion met with much favour, and the comments upon his paper in the scientific and other journals led to discussion of the project, and, in a small way, to its adoption in one or two foreign cities. Meantime the author himself continued his researches, and within the last few months, aided by a pecuniary grant to the committee of the Dog's Home, Battersea, from Mr. KENNETT, whose philanthropic benevolence is so well known, he has been able to carry out his design at the Home on a scale sufficiently large to prove its practical and extensive application. In describing this result, Dr. RICHARDSON first gave a short account of his early efforts to make use of electricity as a rapid means for the extinction of lower animal life, and explained the reasons why he had been forced to the conclusion that the electric shock, rapid as it is, cannot safely be entrusted to the hands of those who have to subject animals to death. He next described the various researches he had made with anæsthetics of various kinds—chloroform, nitrous oxide, ether, methylene, bisulphide of carbon, carbonic acid, carbonic oxide, coal gas, and coal gas combined with chloroform—by which agents death is produced through sleep. Into the lethal chamber which he had now set up for lost and starving dogs, from fifty to a hundred dogs, enclosed in a cage, could be wheeled at once, and submitted to the narcotic vapour, could be made to go into a sleep from which, without any awakening, they passed into death. Between four and five hundred dogs had already been destroyed by this painless process. The chief agent used for narcotising was

Digitized by Google

carbonic oxide, with which the chamber was fully charged before the animals were moved into it. The gas on its way into the chamber passed over a porous surface, from which it took up narcotic vapour containing chloroform, which, also diffused through the chamber, increased the lethal action and maintained the lethal atmosphere within the chamber after it was closed and when not in use.

On the question of the painlessness of the process, Dr. RICHARDSON said that we had the good fortune to be assured by the best of evidence on that matter. The animals were subjected to precisely the same ordeal as were the hundreds of human beings who each day were subjected to anæsthetic sleep from chloroform, laughing gas, methylene, or other narcotic gases or vapour. The animals felt nothing more than the higher animal experiences from narcotism, while they felt none of the reaction of recovery, which is the part mainly complained of by those who have been anæsthetised. In a word, by this process science had made death for the lower creation the truest euthanasia, in which a profound sleep, induced in a few minutes, terminated with equal facility in the sleep of dissolution.

Dr. RICHARDSON concluded by indicating that the same lethal process, carried short of death, might be applied to various animals the flesh of which is used for human food. He had narcotised fourteen sheep (animals which were very readily susceptible to the gas) so completely as to admit of their being killed quite painlessly in the ordinary way; and he fully expected that the Model Abattoir Society, over which he presided, would be able to adopt a system of this character, and to show the way in which it could be made largely applicable throughout the country. If it be sometimes urged against science that she, like nature, is cruel, it must also be admitted that she, like nature, is also kind. It may perhaps be said of her, "She must be cruel to be kind." In the discovery of anæsthesia and of various anæsthetics she may have inflicted some inconvenience, even actual pain, on a limited number of the inferior creation; but here is her return, even to inferior animals. She secures for them, in their want or decrepitude, a death better and easier than falls or ever can fall to the lot of the large majority of the family of man.

Annotations.

"Ne quid nimis."

THE COLLEGE ELECTION.

THE disappointment at the failure of Mr. Oliver Pemberton's candidature for a seat in the Council of the Royal College of Surgeons of England is not confined to the provincial Fellows. Indeed, there are reasons for believing that Mr. Pemberton met with a large measure of support from the metropolitan Fellows. In proof of this, it may be stated that he received only five votes less than a successful metropolitan candidate. The provincial Fellows may fairly complain that they are practically disfranchised; they can only vote at the expenditure of a costly journey to London. The remedy is, however, in their own hands. Let the provincial Fellows generally co-operate with the Association of Fellows, and thereby force the Council to obtain a new charter, allowing voting by voting-paper, before next July. A sub-committee of the Association is actively engaged in preparing a complete scheme of reform, which will soon be ready for presentation to the Fellows. Only by united action can those improvements and reforms be accomplished that will give the Fellows adequate representation on the Council and a corresponding increase of influence and power.

THE PATENT MEDICINES STAMP ACT.

THE repeal of the Patent Medicines Stamp Act is a subject which continues to excite a great deal of interest and much discussion. That such an Act should have been allowed to remain in force for so many years is an anomaly which is hardly conceivable, and is certainly not capable of rational explanation. It must be remembered that it was passed at a time of great financial difficulty, in an age when almost everything was taxed. "We must pay taxes," says Sydney Smith in describing the condition of his times, "upon every article which enters into the mouth, or covers the back, or is placed under the foot. Taxes upon everything which is pleasant to see, hear, feel, smell, and taste. Taxes upon warmth, light, and locomotion. Taxes upon everything upon earth and the waters under the earth. On everything that comes from abroad or is grown at home. Taxes on raw material. Taxes on every value that is added to it by the industry of man. Taxes on the sauce which pampers man's appetite, and the drug which restores him to health." Times have changed since then, and almost all of these obnoxious taxes have been repealed, but for some unaccountable reason the tax on medicines is still retained. It is a subject of congratulation to every right-thinking man that its days are now numbered, and that the Government have at last consented to take decided action in the matter. Reform, to be of avail, must be thorough and sweeping, and it has long been seen that nothing short of the total repeal of the Act will be of the least use. It is a curious fact that England, the land of the free, is the only country where the stamp duty is enforced. In no other country in the world would such an iniquitous law be tolerated even for a moment. In France and Germany there is no Patent Medicines Stamp Act; and even America, with her outrageous tariff system, does not levy a special tax on medicines destined for the relief of pain and the cure of the sick and suffering. Our Act even, curiously enough, applies only to England and Scotland, Ireland and the Channel Islands being happily exempt from its operation. We have already referred at some length in our last issue to the fallacious endorsement it affords to quack nostrums, but perhaps the worst and most obnoxious feature of this law is the facilities it affords for the sale of poisons. By simply affixing a patent medicine stamp, which means no more than a postage stamp does on a letter, any person, however ignorant or however unscrupulous, can sell any quantity of the most deadly poison without a word of warning as to its nature, and without the slightest indication that it is not a harmless or simple remedy. It is a well-known fact that many nostrums contain active poisons; one which is familiar, by name at all events, to everybody contains not only morphia and Indian hemp, but a large quantity of prussic acid. Others are known to have as their active ingredients opium, chloral, and even strychnia. For suicidal purposes certain patent medicines are admirably adapted, and the mortality from their use is enormous. Scarcely a day passes without the record in the papers of an inquest on some poor deluded victim who has been sent to his last account from an overweening confidence in one or other of the much-belauded patent medicines. The facility afforded for obtaining a narcotic, whether it be in the form of opium, morphia, or the deadly chloral, is a consideration which cannot be overlooked. In no other country can poisons be purchased wholesale without a

Digitized by Google

[illegible] inquiry as to the purpose for which they are required, that in England they are sold openly and without contradiction, under the guise of patent medicines. It [illegible] said that the revenue derived from this source is so [illegible] that it would be difficult to find other means for replenishing the exhausted coffers of the Exchequer. The income from the tax, however, is only about £150,000, and from this will in all probability have to be deducted the expenses by no means light, of maintaining the department and [illegible] paid to the common informer. This, however, is [illegible] of the question with which we are in no way concerned. *Our national health is of such paramount importance that [illegible] amount of money, much less a paltry £150,000, could compensate for its degeneration or decay.* On all grounds, then, it is essential that the Patent Medicines Stamp Act [illegible] at once repealed. Delay is fraught with danger, and [illegible] and decided action is imperatively demanded.

[illegible]ERSTRAIN IN FEMALE EDUCATION.

[illegible] pression of overwork is not a new evil, but a [illegible] of all ages. It has varied in intensity and in area of [illegible] from time to time, and has been forced to give [illegible] corrective measures, but blind custom or desire has [illegible] again revived its heedless excesses. Our own [illegible] perhaps more than any other, has yielded to the [illegible] of progress, and has removed many helpful [illegible] of labour, which naturally aid it by preserving its [illegible] power. Women suffer in consequence as well as [illegible] probably to a greater degree. The reason for this is [illegible] their aptitude is generally inferior to that of men, but [illegible] their capacity for work is on the whole smaller. The [illegible] a good deal of relatively blank time in their lives [illegible] of their periodic indispositions. There is a tendency with some to make light of such poor physical [illegible] when they seem to impede the march of [illegible] it is for studious work that women hunger most. Exceptions to rule are pointed to, of women who have [illegible] very hard studies and escaped uninjured. But many [illegible] not escape. Dr. Thorburn of Manchester, in a [illegible] this subject, has shown that the bad effects of [illegible] on women are largely due, and are felt by themselves due, to its unremitting continuance during the [illegible] periods. At such times the nervous system is [illegible] of energy in an equal or even greater proportion [illegible] any other. The obvious suggestion is that [illegible] measure should for the time be relieved in a [illegible] degree. If this precaution be not taken, not important function, but all, will probably suffer. Under [illegible] like circumstances of strain from worry or work, the [illegible] of the climacteric are apt to appear prematurely, and [illegible] to continue and preclude by their presence the [illegible] discharge of any occupation whatever. How best [illegible] difficulty be met? Not certainly by denying to women the highest type of education. The *kind* of [illegible] does not constitute the danger, but the excessive [illegible] ardour with which it is apt to be maintained. It [illegible] to see how, in a large class of female students, the [illegible] variations of energy in each case can be understood [illegible] allowed for. No such mechanical regulation, however [illegible] statistically correct, could well be introduced into [illegible] arrangements. The better plan would be to keep the [illegible] rate and quantity of work during the whole [illegible] period somewhat under the full mental capacity of [illegible] so that the reserve energy unused during three-fourths [illegible] of the time might be available to supplement the [illegible] vigour of the other fourth. The frequency of [illegible] is a separate consideration which should not be [illegible]. Participation in these contests should be [illegible] dependent on the health at the time of individual competitors, a matter not difficult of decision. Moderate physical exercise in tennis grounds or suitable gymnasia should in every ordinary case form the co-efficient of a healthy scholastic training.

PRECAUTIONS AGAINST CHOLERA AT MONACO.

THE little Principality of Monaco, always distinguished among other health-resorts of the Riviera by the scrupulous order and cleanliness of its streets, has adopted, early in the day, energetic measures to ward off the danger of cholera. Though the health of the population is exceptionally good, the authorities are alive to the risks they incur. The sewers, the public latrines, and urinals are now disinfected every day by agents of the Government. Narrow passages and streets in the old town have all been whitewashed, and the houses of the poorer classes and lodging-houses have been subjected to careful inspection. Cesspools are more frequently emptied, but this operation is preceded by the use of a large quantity of sulphate of iron. The decrees rendering it a penal offence to allow the overflow from cesspools to run into the sewers, or to empty out into the sewers any night soil, have been republished and extensively circulated throughout the Principality. The inhabitants are further called upon to keep their bedroom windows open all day, to boil and filter their drinking water, and to thoroughly cook their food. The markets are strictly watched, fruits and vegetables not absolutely sound, that seem either over-ripe or insufficiently ripe, are at once seized and thrown into the sea. Private shops are also inspected daily and large quantities of fruit have been taken away and destroyed. All who have night duties to perform—policemen, railway servants, &c.—are compelled to wear their woollen clothing in spite of the heat, and they are forbidden to drink crude water, and to touch raw fruits or undiluted spirits. All luggage and goods coming from Toulon and Marseilles must be disinfected before they are allowed to enter the Principality, and throughout the most scrupulous cleanliness is observed. Unfortunately, all these precautions are not sufficient. The entire system of drainage must be reformed before true security can be enjoyed. So long as house drains are not trapped and ventilated, so long as cesspools continue to exist, the Principality will not be free from the menace of epidemic disease. Nevertheless, so far as surface cleanliness and careful scavenging are concerned, it is admitted on all sides that Monaco and Monte Carlo stand pre-eminent among all the other towns of the Riviera.

CRUELTY TO CHILDREN.

As Alderman Cotton, M.P., quaintly put the matter, eighteen feet of signatures were appended to a requisition to the Lord Mayor of London to call a meeting to form a London Society for the Prevention of Cruelty to Children. The proposed meeting has been convened and the Society is formally constituted. We trust it will soon get into working order and fulfil the purpose in view. Mr. Fowler, M.P., was probably right in thinking that the mere thought of being watched would deter parents from many acts of cruelty; but we venture to think much more than simply moral influence will need to be exerted if any real good is to be done. There would seem to be a difference of opinion at the very outset as to what is required. Lord Shaftesbury thinks the existing laws sufficient, while Cardinal Manning considers that they will not serve to do the Society's work. We trust that before long this new beneficent organisation will show its vitality by introducing some salutary reforms, particularly with regard to the little children who are turned out into the streets to earn a fixed sum, on gaining which their prospects of bed and board depend.

THE COLLEGE OF SURGEONS MUSEUM.

IT is scarcely necessary to state that Sir Henry Thompson's recent lectures at the Royal College of Surgeons of England constitute an important and eventful contribution to the literature of the surgery of the urinary apparatus. In these lectures Sir Henry set forth the whole of his remarkable experience. Not the least interesting circumstance connected with the lectures was the presentation to the Museum of the College of a cabinet containing many hundred calculi. The two principal matters brought forward in the lectures were—first, the great improvement in the statistics of the operation of lithotrity in the modern mode of free crushing and complete evacuation of the fragments; and second, the value of the method of digital exploration of the bladder in cases where the nature of the vesical trouble is obscure. The lecture on the removal of tumours of the bladder by operation was of especial interest, and was illustrated by microscopical specimens and drawings, in the preparation of which Dr. Heneage Gibbes largely assisted. The cabinet containing Sir Henry's unique collection of calculi was shown last week at the exhibition of the additions made to the Museum during the past year. Respecting this collection, Mr. Flower, in his annual report to the Museum Committee, says: "Upon the conclusion of his course of lectures on the Surgery of the Urinary Organs, Sir Henry Thompson presented to the Museum the cabinet containing his very important collection of calculi, the result of 812 operations by lithotrity and lithotomy, all neatly mounted in glass capsules, and every specimen accompanied by authentic details of the case. The value of this series as illustrating an episode in the history of surgery needs no comment."

PARASITES IN FISH AND FLESH.

THE free discussion of any vexed question is rarely an unmixed good. This arises from no defect in the principle itself, but from the fact that there are usually persons who rush to the front and speak with an authority that is only self-accorded. In every-day life such conduct savours of mere impudence; but when, as has happened in regard to the so-called "mackerel scare," the hasty utterances of uninformed persons have resulted in the production of much misery amongst the poorer classes, who in great part rely upon a fish diet, then we may justly characterise such conduct as blameworthy. We would willingly have let this matter drop, being well satisfied with the trustworthiness of the statement of the Inspector of Fisheries, supported as it has been by the more detailed explanation supplied by Dr. Cobbold; but it appears that in consequence of the "scare" several tons of healthy fish have been weekly sacrificed, the poor absolutely refusing to purchase mackerel. On this account it is a public duty to call further attention to the subject. After the conferences which took place at the Fisheries Exhibition last year, it seems strange that the good work then done in connexion with fish parasites should be so soon disregarded. Numerous specimens of the particular parasite (Filaria piscium) around which so much discussion has arisen were exhibited at last year's show, not only from mackerel, but also from the herring. There are many points requiring attention, but that which calls for immediate remark is the question as to the amount of temperature necessary to destroy parasites of all kinds infesting the flesh of fish and other animals used as food. So far as Dr. Cobbold is concerned, nothing could be more explicit than his recognition of foreign research in this matter. Discarding his own efforts, which, after all, were by no means unsuccessful (as the confirmatory and more extended labours of Dr. T. R. Lewis at Calcutta have shown), he rested his recent statements chiefly on the investigations of Professor Perroncito of Turin. This *savant*, after a series of elaborate experiments, which are recorded in the *Osservatore Gazzetta d. Cliniche di Torino* and in several scientific and professional periodicals, finally established the fact that cysticerci and other parasites infesting flesh perished invariably at a temperature below 50° C. (122° F.) It must be borne in mind that Professor Perroncito himself had been rather severely taken to task for having, on more slender and initiatory experimental work, previously asserted that, "if it is not certain that the cysticerci die at from 80° to 100° C., we are quite sure that they dry up and become completely mummified at 125°, 130°, and 150° C. (257°, 268°, and 302° F.)" It must be remembered, moreover, that the final results were not arrived at until after certain published statements by Professor Pellizzari, who conducted researches in relation to sanitary measures effected by the Municipal Commission of Florence. In these investigations Pellizzari was assisted by Dr. Tommasi, the translator of Dr. Cobbold's lectures delivered at the Middlesex Hospital. In Dr. Tommasi's *Appendice* to another of our English author's volumes ("Parasiti interni degli Animali Domestici") readers of Italian will find a full account of these researches. Referring to these investigations, by which it was concluded that a high temperature was necessary for the destruction of parasites, Professor Perroncito says: "Towards the end of 1874 Professor Pellizzari disputed the results of my investigations made in 1872, and agreed with Dr. Lewis, who had already stated that the cysticerci exposed to 55° C. can be held to be dead after the lapse of five minutes. It may be argued that the Italian *savant* was not dealing with nematoid worms, and that therefore his labours did not affect the fish question. Such an excuse is altogether inadmissible, seeing that Perroncito found 50° C. alike destructive to Trichina spiralis, to Strongylus filaria, and to two species of filaria. The filaria of the mackerel is just as easily destroyed by heat as is any other species of the same genus of parasites, wherever it may happen to be found.

DISEASE AND WATER IN INDIA.

IN connexion with the interest which now attaches to the condition of tank water in India, we would refer to an excellent lecture on the relation of wholesomeness of water and the maintenance of health which was delivered some two years ago to the native population by Dr. M. C. Furnell, Sanitary Commissioner for Madras. The lecture fully confirms by means of its numerous details the views that have so often been expressed as to the facilities which are afforded by the tank water supplies of India for the diffusion of infectious diseases, and especially of cholera and of enteric fever. Men and women habitually wash their clothes and garments and then bathe their bodies in the same tank as that from which they take their water for domestic purposes; the approaches to some of the tanks are filthy in the extreme, and Dr. Furnell has even seen women collecting water for home purposes, when the contents of the tank have at the same moment been in use for ablution being foul to the senses of sight and smell. So long as conditions such as these remain, it must be obvious that one of the most fertile and well-known channels exists for the rapid diffusion of cholera, and it is impossible to prove that the aerial communication of this infection is the one which is most commonly in operation. The multiplication of such lectures to the native population would be most useful, and we are glad to note that in addition to the circumstance that the Bombay Government ordered Dr. Furnell's lecture to be translated into the Vernaculars of Northern and Southern Deccan, Gurjerat, Sind, and Arabic, it has also been reproduced in several other languages.

THE CHOLERA EPIDEMIC.

THE epidemic of cholera in the south of France does more than maintain itself; it increases, and it has diffused itself over a somewhat wider area. But for all that, it is still a limited outbreak, and the hope that it may in the main be confined to the neighbourhoods first attacked may perhaps be realised to a greater extent than was at first thought possible. Cholera, however, has more than once remained in a comparatively quiescent condition prior to a sudden and widespread extension, and hence it will be well to be prepared for all contingencies. So far the rumours as to its extension to Paris and towns in other countries do not seem trustworthy, and hitherto no case has been brought into the United Kingdom. It is true that early next week a vessel, alleged to be infected with cholera, may be expected at Cardiff; but since the occurrence has now been anticipated for several days, it ought to be quite possible for the sanitary authorities so to deal with the case as to prevent any importation of the infection. It is essentially on our being prepared beforehand that we must rely both on our coast and inland; and with a view to this the Local Government Board have re-issued to all sanitary authorities the excellent memorandum of Precautions against the Infection of Cholera which was prepared last autumn by Dr. Buchanan, their medical officer, and which specially calls attention to the duties of sanitary authorities in the matter of the adoption of all such measures of prevention as will enable them to check extension of infection in case any mild attacks of cholera escape the vigilance of port and other authorities on the coast line.

NORTH LONDON CONSUMPTION HOSPITAL.

THE affairs of this hospital have been in an unsatisfactory condition for many years. It appears from a letter to the governors, signed by the chairman of the Committee of Management and also of the Committee of Investigation, that there has been practically no management whatever from the date of the foundation of the hospital up to December, 1883. For example, an Investigation Committee, appointed a year ago by the governors, has brought to light "that the books and accounts had been kept in a most irregular way; that the system adopted by the secretary made it very hard to find whether, or when, donations paid to him had been paid to the credit of the hospital; and that the irregularities were such as to make it very difficult to exculpate the character of the secretary, although all the investigation tended to prove was that his methods, and not his character, were at fault. The committee were equally culpable, as the meetings for upwards of ten years had been most irregular, and without a quorum, and all natural stimulus to precision and care was withdrawn from the secretary." No meetings of governors seem to have been held till quite recently. Unfortunately, and possibly almost necessarily, the medical staff must share the responsibility of the past mismanagement, and there are many points connected with the discharge of their duties at the present time which the Committee of Management will have to remedy without loss of time. The senior physician, Dr. Timms, states in a letter to the Hampstead papers that he was responsible for the management up to 1868, and the majority of abuses stated above were rendered possible by the action of the committee when he had them under his own control. The publication of the private address of each member of the staff on the foil of the out-patients' notes, and their exhibition upon large boards in the out-patients' room of the hospital, are practices which must be unreservedly condemned. It is further matter for regret that, with one exception, the chief speakers at the meeting of governors on the 1st inst. who spoke against unity of purpose and compromise were those members of the honorary staff who are governors. It is an unfortunate omission from the rules that no date is fixed for the retirement of members of the staff, or for their removal in case of necessity. New regulations have, however, been proposed to remedy these omissions; and meanwhile it will be a graceful act if the senior physician will tender his resignation and thus become eligible for election as consulting physician to the hospital. We fully endorse the wisdom of the decision arrived at by the governors, to forget the past and to rest content by securing the best of good management for the future. There are two points of great public importance which arise out of the revelations made in connexion with the management of this hospital. First, the fact that the Hospital Sunday and Hospital Saturday Funds have for ten consecutive years made substantial grants to this hospital, which throughout the whole period never held an annual meeting, never had a properly constituted committee, never possessed any reliable accounts, and never produced evidence that the contributions received were paid to the credit of the hospital, proves beyond question that stricter inquiry must be made by the Councils of these Funds in future before they make a grant. Someone should certainly be sent on behalf of each Fund to inspect a hospital and the books before a grant is made. On the other hand, it is matter for congratulation that, through the efforts of Mr. Burdett, Mr. F. D. Mocatta, Mr. B. A. Lyon, and other members of the Investigation Committee, there is now every prospect that the North London Consumption Hospital will be managed upon the best known principles of hospital administration. Indeed, there is reason to hope it will become as large, important, and prosperous a hospital in the north of London as the Brompton Hospital, which may be regarded as the South London Consumption Hospital.

ISOLATION ARRANGEMENTS AT LIVERPOOL.

As the result, apparently, of a visit from Dr. Mouat of the Local Government Board, the Corporation of Liverpool have at last made some arrangement with a view to meeting the wants of their district in the matter of the isolation of infectious diseases. The intention seems, in the first instance, to be limited to dealing with small-pox, and even as regards this disease the accommodation is to be only of a temporary character. But now that the Corporation have been compelled to assent to the principle that it is the duty of the sanitary authority, and not of the Poor-law authority, to provide the means of isolation necessary for the protection of the public against the risk of infection, it is to be hoped that they will not cease in their labours until they have made proper and sufficient permanent provision for their district in this respect.

TRAINED NURSES FOR THE SICK POOR.

THE passing of Gathorne Hardy's Act of 1867 may be said to have created a revolution in the method of dealing with the sick poor in the metropolis, providing as it did for their treatment in establishments under separate management and quite distinct from the workhouses. The various boards of guardians have loyally carried out the provisions of the Act, and in all districts of London are to be found parish infirmaries specially designed and erected for the care and treatment of sick paupers, a medical superintendent being in charge of each infirmary. The finest institution of the kind is that provided by the guardians of St. Marylebone at Notting-hill, which was opened by the Prince and Princess of Wales in 1881, that occasion being the first on which Royalty had assisted at any ceremony in connexion with a Poor-law establishment. The St. Marylebone guardians soon found the same difficulty that had been experienced

Digitized by Google

elsewhere, of obtaining suitable trained nurses, of whom they require a staff of fifty-six; and, finding that the efficiency of the working of their large infirmary was likely to be much impaired by this scarcity of nursing help, they decided upon the step—till now novel in Poor-law administration—of erecting a building as an institution for training nurses. This establishment, which comprises accommodation for forty probationers and nurses, with every proper convenience for their comfort, and includes lecture-rooms, has been erected adjoining the infirmary, at a cost of £12,000, and will be opened by H.R.H. Princess Christian on the 22nd inst. In the regulations for the administration of this much-needed work, the guardians are acting in connexion with the Council of the Nightingale Fund, who are associated with them in this desirable object, the working of which will be watched with great interest by those who know the difficulties connected with the nursing of the sick and infirm who come under the care of the Poor-laws.

SUNSTROKE.

THE past few weeks have not been unattended with the perils to health which accompany continuous warm weather. Sunstroke, comparatively rare in our temperate climate, has already been reported. It is somewhat surprising that, in the circumstances under which so many of us, particularly children, live and go about, we do not hear of it oftener. Among the poor, bareheaded children are at least as common as those with hats. They are "only about the doors," and care is disregarded. In a wealthier grade it is not unusual to find infants wheeled about in perambulators guiltless of a hood, even in a bright and hot noon-day. Persons more advanced in age are apt to be careless in their own way. Notwithstanding the sanitary value and the comfort of broad summer hats, athletes at times, and for long at a time, interpose no more than the skull between a delicate brain tissue and a temperature of 100°, or more, in the sun. Young ladies now more than ever raise over the crown the hair which naturally rests upon the nape of the neck and there protects the seat of the vital nerve-centres. Fortunately these have another means of protection from solar heat in the parasol. Sunstroke is best treated by prevention, and enough, perhaps, has been said to direct public attention to the need in such a season as this of adapting means to this end.

CRUEL QUARANTINE IN SHETLAND.

THE evil results of ignorance and want of human intercourse have found unseemly illustration in connexion with a recent outbreak of typhus fever in Shetland. Two cases of disease were attended by circumstances of wilful cruelty which appear hardly credible. Dr. Hanson of Mid Yell became infected while visiting among the victims of the epidemic. During his illness he received no aid or attention whatever from any islander, save his own domestic, the schoolmaster, and a kind lady, who amid much discouragement supplied the sick man with necessary food. After some time a nurse was procured from Edinburgh, and, thanks chiefly to her careful management, the issue of this case was satisfactory. To all these measures of mere humanity the people of Yell offered persistent opposition. They refused all assistance, abused those in attendance, and would hardly allow provisions to be taken to the doctor's house. All this, be it remembered, to the man who had spared himself least in attention to those who were stricken with the same disease, and who owed his illness directly to his professional self-forgetfulness. The island of North Yell was the first attacked. It was here that Dr. Hanson contracted the fever. One would have expected that here at least the pressure of a common evil might have led to some feeling of sympathy with the sufferers; but it was not so. Another gentleman, who officiated both as minister and medical attendant, succumbed to the prevailing malady after five days' illness. During this period not one of his parishioners would even come to inquire about him. After his death the same panic-stricken fear induced them to forbid all intercourse with his family, even for the purpose of burying the body. A coffin could hardly be obtained, and decent interment might never have been accomplished if it had not been for the prompt and efficient help rendered by some Scottish fishermen who were cruising along the coast. The history of epidemics can probably furnish few more pitiful details than these. Happily for the reputation of mankind, it has also afforded instances of heroic regard for duty. It is difficult to believe that, even at the remotest point of our islands, every heart can be so dead to generous feeling as to acquiesce entirely in the barbarous and cowardly quarantine lately instituted there. Precaution let there be, and first of all cleanliness and fresh air in every dwelling; but, in the interests of health, no more of this superstitious and heartless dread of an evil which may and must be remedied.

THE HEALTH EXHIBITION AND THE HOSPITALS.

THE grand *fête* in aid of the London hospitals, to which we alluded last week, will be held on the evening of Wednesday, July 23rd, under the special patronage of the Prince and Princess of Wales, to whom the initiative is due, and who have announced their intention of being present. On this, the second of the two special Wednesday evenings (the first having been devoted to the *conversazione* given by the Council of the Society of Arts and the Executive Council of the Health Exhibition, on the 9th inst.) for which season and other tickets are not available, the price of admission will be raised to ten shillings; and as doubtless the visitors, having once gained entrance, will readily find other opportunities of loosening their purse-strings in so good a cause, we anticipate a very handsome total. The money thus obtained will be handed to the Lord Mayor for distribution among the various metropolitan hospitals by means of the organisations of the Saturday and Sunday Hospital Funds. The grounds will be illuminated by 20,000 variegated lamps, and special effects will be introduced in connexion with the illuminated fountains. The doors of the Exhibition will be opened at 7.30 P.M., the *fête* commencing at eight. The project must necessarily command our warmest approval and heartiest good wishes; nevertheless, we still venture to hope that at the final adjustment of accounts the claims of the hospitals to a share of the profits—and, judging from the extraordinary popularity of the Exhibition, its earnings appear likely to reach a very large amount—may not be thereby discounted or in any way cast into the shade.

CHOLERA REMEDIES.

ATTENTION has been called by M. Klaczko of Vienna to the prophylactic value of petroleum or paraffin, based on the alleged fact that the workers at the petroleum wells of Galicia have "always enjoyed perfect immunity from cholera." The suggestion is that petroleum acts as a germicide. M. David Dinh of Paris writes to us respecting the use of powerful antiseptic agents in the disease. He avers that sulphate of copper acts merely in this way, and is often inoperative, as in the case of the late M. Thuillier. The perchloride of mercury, or rather the red iodide, being the most powerful of all germicides, he asks whether it can be shown that syphilitic subjects under mercurial treatment enjoy an immunity from cholera, and suggests that iodoform, a less dangerous drug and more easily administered, should be tried.

CORONERS AND MAGISTRATES.

AT an inquest recently held at Elmer's End Station on the South-Eastern Railway, on the body of a platelayer who met his death by accident, one of the jurymen asked if the doctor who saw the deceased should not have been called. The coroner, Mr. E. A. Carttar, replied that it was not necessary in the present instance, and in the course of his remarks stated that the county justices not only surcharged him with medical fees which they deemed had been unnecessarily expended, but that they had gone so far as to take exception to his holding inquests in cases where the mode of death appeared evident, and had intimated their intention of making him pay the whole expenses of the inquiry. If these alleged facts be true, and we see no reason to doubt that they are, the sooner the legal obligations of coroners are made public the better. It is perfectly monstrous that a county magistrate should be in a position to criticise and pass judgment on the acts of an officer, holding a post of high responsibility. Fortunately, however, an appeal can be made to the Home Secretary, who can, if he sees fit, make an order for the disbursement of moneys paid by a coroner in the exercise of his discretion and the discharge of his duty. Now, coroners are usually paid by salary, and therefore they are not open to the charge of holding unnecessary inquests for the sake of increasing their emoluments, and for this reason they should be supported by the public and the medical profession against the arbitrary and overbearing interference of persons who are often imperfectly acquainted with the merits of the case in question. If such exhibitions of false economy are allowed to go unchallenged, the coroner's court will soon become a dumb show, to say nothing of the incentives that would be offered to the development of crime by reason of the check put on its detection.

M. PASTEUR'S HYDROPHOBIA EXPERIMENTS.

THE experiments which M. Pasteur is reported thus far to have made are said to be an unbroken success. Fifty-seven dogs have been the subjects of investigation. Of these, nineteen were rabid, and by these thirty-eight healthy animals were bitten under uniform conditions. Of the thirty-eight, one-half the number had been previously inoculated or "vaccinated" with attenuated virus; the other half had not. The latter, without a single exception, died with unequivocal signs of rabies, whereas the nineteen others remain as well as ever. They will be watched for a year by veterinary surgeons to see whether the inoculation holds good permanently or only temporarily. If rabies be not spontaneous in its origin, and if the experiments of Pasteur all turn out successful, there seems no reason why canine madness should not be extirpated from our midst.

THE BOWER AND KEATES CASE.

THE entire medical profession will learn with sincere regret that this case has on the appeal of the plaintiff been set down for a third time. When it was heard before the Lord Chief Justice a verdict was given for the defendants. At the first trial Mr. Justice Field left these questions for the jury to decide:—1. Did the defendants know at the time of the operation, or ought they to have known, that the child was suffering from diphtheria? 2. Did they know, or ought they to have known, that suction of the tube would be dangerous? 3. Was the plaintiff's illness caused by sucking the tube? 4. Could his illness have been prevented or diminished by warning and precautionary measures? The result was that the jury did not agree, and were discharged. The grounds for the recent decision of the Divisional Court, composed of Mr. Justice Field, Mr. Justice Manisty, and Mr. Justice Lopes, were in general terms that the Lord Chief Justice did not lay the case clearly before the jury, and, in particular, that he ought to have directed their attention to the following issues: (1) Ought Messrs. Bower and Keates to have told the defendant that the case was one of diphtheria, and that he ran a risk in sucking the tube? and (2) ought they not to have taken precautions to avert the disease, or lessen its severity if contracted? Concerning the legal technicalities, we do not wish to say a word, the more so as the case is again *sub judice*; at the same time, we agree with Mr. Justice Field that "it was a pity the action should have been brought, no doubt under the influence of mistaken feeling." This opinion will be fully endorsed by Messrs. Bower and Keates' professional brethren.

ISOLATION AND INFECTION AT PRESCOT.

THE Prescot rural sanitary authority has wisely decided to erect a hospital for infectious diseases, and in its capacity as a Poor-law authority it has determined no longer to admit non-pauper infectious cases into the workhouse. One member of the authority maintained that if patients were admitted into an infectious hospital belonging to the sanitary authority they would be just as much paupers as if they were admitted into the workhouse, on the ground that wherever expense is incurred by an authority or by the ratepayers, those profiting by it are virtually paupers. Quite apart from the fact that the law has decided otherwise, it is curious that anyone should hold such a view. The adjoining urban district of Prescot is less fortunate than the rural one in its decision. Instead of either combining with the rural district in providing a hospital, or erecting one of its own, it has sought to make an arrangement with the authorities of the Netherfield Institution in Liverpool, a city where infectious hospitals have already been much overcrowded, and where, in consequence, there is grave reason to believe that one infection—namely, that of small-pox—has been spread to the surrounding community. The arrangement, being also contingent on empty beds being available, will probably fail at some critical moment. Indeed, the whole scheme savours of an ill-matured plan, for the hospital authorities advise that if any difficulty should arise in the removal of patients, "cabs can be used, if properly disinfected afterwards." We should like to know the process by which a small-pox infected cab, with its cloth and stuffed seats and linings, can be "properly disinfected"; and we can only wonder that such advice can emanate from a hospital which professes to prevent the spread of infection.

INSURANCE WITHOUT MEDICAL EXAMINATION.

UNDER the new regulations for Government Life Insurance, a novel experiment is being tried, the result of which will be watched with interest. Insurances for sums not exceeding £25 are now granted at any post office savings bank without any medical examination. If, however, an insurant should die before the second annual premium becomes payable, the amount of the first premium, and no more, will be paid to his representative; should the insurant die after the payment of the second, but before the third premium becomes due, the representatives will be paid only half the amount of the policy. After the payment of the third premium the policy is entitled to full benefit. It is nevertheless provided that in case of death within two years of an insurant who has not been medically examined, if it can be proved to the satisfaction of the Postmaster-General that the death was caused by accident, the full amount of the policy will be paid. Persons proposing to insure for sums not exceeding £25, and preferring that their policy should have the full benefit of insurance at once, can

Digitized by Google

undergo a medical examination by payment of a fee of half-a-crown to the medical examiner. The rules do not explain the nature of the arrangement by which the fee for medical examination to be paid by the insurant is to be supplemented. The new system by which insurances may be granted through post office savings banks affords great facilities for industrial insurance combined with absolute security, which, it may be hoped, will commend the system to the working classes. We are glad to observe that no insurances will be granted upon the lives of children under eight years of age, and the amount is limited to £5 upon children aged between eight and fourteen years.

OPHTHALMOLOGICAL SOCIETY.

THE annual meeting of this Society was held on July 4th. Mr. Streatfeild, the Treasurer, read his report, showing that the Society was in a prosperous state. The report of the Council, read by Dr. Abercrombie, stated that the nucleus of a library had been formed by the donation of some books by the President and a few others. The rules relating to the library were practically those governing the library of the Medical Society. It was also announced that the first Bowman lecturer would be Mr. Jonathan Hutchinson; the lecture will be delivered in November next. The following is the list of officers and Council elected for the year 1884–85:—President, Jonathan Hutchinson, F.R.S. Vice-Presidents: Sir Wm. Bowman, Bart., F.R.S.; C. E. Fitzgerald, M.D; Henry Power; Thomas Reid, M.D.; T. Shadford Walker; J. C. Wordsworth. Treasurer: J. F. Streatfeild. Secretaries: John Abercrombie, M.D.; W. A. Brailey, M.D. Other members of Council: George Cowell, G. A. Critchett, R. Marcus Gunn, George Johnson, Stephen Mackenzie, Charles Macnamara, E. Nettleship, Priestley Smith, Simeon Snell, J. Sympson, John Tweedy, W. Spencer Watson.

"VIEWING" THE BODY.

THERE is a great outcry against the practice of "viewing" a body as the legal basis of a coroner's inquest. We are not prepared to defend the practice in question; it is probably useless in nine cases out of ten, and often a mere farce as conducted in the tenth instance. Meanwhile, we cannot but think that it is a strong and impolitic measure for coroners to take upon themselves to dispense with the "view" at caprice or discretion. There should certainly be uniformity in the procedure. It is certain there must be something equivalent to a "view" for identification and other purposes, or it may happen that some day a criminal dies and is buried on "a coroner's certificate" without actually being dead, except to the world of informers and police, until such time as he may reasonably expect to be forgotten. A body there must be; and good evidence as to its character and condition must be forthcoming if the "view" is to be abandoned.

WHISKY AS AN ANÆSTHETIC.

IN his address as President of the Ninth Annual Session of the Arkansas State Medical Society, Dr. Keller is reported to have spoken as follows on the subject of whisky as an anæsthetic:—"To Dr. Link of Indiana are we indebted almost entirely for having gone far towards placing whisky not only along with ether and chloroform as an anæsthetic, but also in discovering its antiseptic power, equally as safe and effective as any other. So well satisfied is that gentleman from long use of it as his only anæsthetic and antiseptic in amputations, that he asserts he has discarded all others, and in his reports of several hundred cases he says that he has seen no manifestation of pain during any amputation—no unhealthy action in any stump, and not a single death to mar the report." The manner of anæsthetising the patient seems to be to administer one or two ounces of whisky by the mouth every ten minutes "until complete drunkenness is reached," and then, with or without one or two inhalations of ether or chloroform, to proceed to operate. On the face of it, this procedure appears to be open to righteous condemnation. It is well known that acute gastritis may be set up by such means, and the onus of proving that such large imbibitions of alcohol are inoffensive rests with Drs. Link, Keller, and others who may choose to employ the drug. It is possible—anything is possible in medicine—that such treatment may be innocuous; but until more accurate knowledge is forthcoming we prefer to believe the contrary.

CONVERSAZIONE AT THE HEALTH EXHIBITION.

A VERY successful and pleasant entertainment was given in the buildings and gardens of the Health Exhibition on Wednesday evening last, by the Executive Council and the Council of the Society of Arts. Most of the exhibitors kept their stalls open, and those having machinery in motion kept it running as during the day. The beautifully illuminated gardens and their fountains afforded a *coup-d'œil* to which Londoners are but little accustomed; indeed, it is only quite lately that they have had any opportunity at all of proving that they are capable of appreciating such form of amusement, and of taking their pleasures not sadly, but rationally and temperately. The bands of the Grenadier Guards and the Coldstream Guards, with those of the 1st Regiment of the French Engineers and the 7th German (Magdeburg) Cuirassiers, discoursed excellent music; while a novelty was afforded by the performance of a Chinese band in the gardens by the Chinese Court. A perfect summer evening enhanced the enjoyment of many thousand guests.

PARKES MUSEUM OF HYGIENE.

A GENERAL meeting of this Corporation was held on Wednesday last, when the annual report was read and dopted. As was to be feared, the lamented death of the President, H.R.H. Prince Leopold, is regarded by the Council as an incalculable blow to the progress of the Museum. A class of Hygiene is about to be formed at the Museum in affiliation with the Science and Art Department, South Kensington. Considerable developments have been made in the book department of the Museum. The excellent library and reading-room have been thrown open to students at the small annual fee of 5*s*. Good work has been done by the holding of lectures and demonstrations. Special thanks are due to the Treasurer, Mr. Berkeley Hill, to the Hon. Librarian, Dr. Louis Parkes, and to the Hon. Secretary, Dr. Dawson Williams. No less than 7000 persons have visited the Museum during the past session. Nevertheless, owing to the expenses incurred in removing the institution to new premises, the funds of the Corporation are not in a very satisfactory state.

THE DIFFUSION OF SMALL-POX.

WE are glad to see that the Local Government Board have instructed Mr. Power to resume his inquiries as to the diffusion of small-pox from the hospitals of the Metropolitan Asylums Board. The inquiry commences with the Fulham Hospital; and, as on the occasion of the first investigation in 1881, circular letters have been issued to all medical practitioners within a wide radius of that establishment asking them for confidential information concerning all small-pox attacks which may come under their observation.

Digitized by Google

The inquiry is one of such immense importance both for the purposes of the metropolis and elsewhere, that we trust all will join in rendering Mr. Power every assistance they can by periodically sending him the information he needs on the forms which are prescribed, and which are supplied to all medical practitioners.

TEMPORARY PRESERVATION OF POST-MORTEM SPECIMENS.

IN the second number of *The Asclepiad*, amongst the Opuscula Practica, Dr. Richardson describes a method of temporarily preserving specimens taken from the dead body. A wide-mouthed bottle, with a large stopper which is made to fit evenly by the use of a little glycerine, is filled with a mixture of common coal gas and one drachm of ammoniated chloroform. The stopper is then tied down. Any part which is desired to be preserved is placed in a fold of soft muslin and gently pressed so as to remove superfluous fluid. The next point is to introduce the part enveloped in the muslin into the bottle without displacing more of the gaseous contents than necessary. The ammoniated chloroform is supposed "to prevent the breaking up of the water of the tissues," and the carbon monoxide of the coal gas preserves the colour of the specimen.

SIR HENRY ROSCOE.

HER MAJESTY has conferred the honour of knighthood upon Professor Roscoe of Owens College, in consideration of the services rendered by him in connexion with the Technical Education Commission. Born in 1833, Professor Roscoe took the degree of B.A. at the University of London in 1852, and subsequently graduated Ph.D. at Heidelberg. In 1859 he was appointed to the chair of Chemistry at Owens College, and his knowledge of the actual working of the German system has no doubt contributed materially to the determination of the course to be followed by the Victoria University. Sir Henry Roscoe's latest and perhaps most important work is the "Treatise on Chemistry," forming six large volumes, which he wrote in conjunction with Professor Schorlemmer. The first part appeared in 1877, and the concluding volume a few months ago.

THE DRAINAGE OF OXFORD.

IN an annotation which appeared in our issue for June 14th, p. 1086, we urged the University authorities of Oxford to specially bestir themselves in the matter of the water-supply of the city, and we are glad to learn from a letter which appears in a contemporary that, at the Vice-Chancellor's suggestion, the Hebdomadal Council have appointed an informal committee of scientific persons to inquire into the water question. In the meantime, it is understood that the Hog-acre stream, with its ill-flavoured contributions, is no longer to be drawn upon, and that the water of the Railway Lake, the reservoir from which the city is supplied, is henceforward to be supplemented by some other of the network of streams by which Oxford is surrounded.

BENGAL CINCHONA PLANTATIONS.

THE annual report of the Government cinchona plantations in Bengal, drawn up by Dr. King, shows a prosperous state of affairs. Considerable changes were effected during the year in the proportions of the different species of cinchona under cultivation. In the plantations at Mungpoo and Sittong some 232,200 red bark trees were uprooted, and these were replaced chiefly by the yellow bark variety. The new plantation at Rungjung was also planted out with 42,200 trees of the yellow variety. Calisaya ledgeriana has been found by analysis to yield much better supplies of quinine than the red bark. The total number of cinchona trees of all sorts at the close of the year was 4,740,811, of which 3,532,000 are cinchona succirubra. The entire produce of the plantations for the year was 305,160 lb. of dry bark.

THE SOURCE OF BILE ACIDS.

ACCORDING to Dr. Jensen (*Philadelphia Medical World*), Pettenkofer's test for bile also holds good for peptones. It had long been surmised that the slight bitterness of the true peptones is due to the presence of bile in one of its initial stages, as manufactured by the process of digestion. Experiments have been made on boiled albumen, flesh, and a solution of gelatine, after being converted into peptones in separate bottles by a minute proportion of Dr. Jensen's pepsin. The albumen peptone gave a much stronger reaction with the bile test than did the peptone from flesh; and the gelatine peptone was almost unaltered by the test. It is thus thought that the albumen of food furnishes the chief elements for the bile.

WOOLSORTERS' DISEASE AT BRADFORD.

THE inquest on a case of woolsorters' disease at Bradford, which was adjourned from June 18th to the 2nd inst., has been yet further adjourned to the 21st inst., in order to give manufacturers the opportunity of stating the precautionary measures in force at their factories to prevent the transmission of the disease. On the 2nd much evidence was given by medical witnesses, including Drs. Bell, Wilmot, Cadman, and Britton; and no pains are being spared to make the inquiry an exhaustive one. Since this inquiry commenced another fatal case has occurred in the same town.

NORTH-WEST LONDON HOSPITAL.

WE announced last week that a conference between representative members of the profession and a small subcommittee of the Board of Management of the North-west London Hospital was being arranged with a view of so framing its rules and regulations as to bring them into harmony with those of other institutions. We learn that Sir Spencer Wells, Mr. John Marshall, and Mr. Ernest Hart have consented to join in this conference.

MEDICAL LIFE PEERS.

WE understand that Dr. Lyons, M.P., has given notice of an important amendment to be inserted in the Medical Act Amendment Bill, to the effect that two physicians of over twenty years' standing should be made life peers and act as lord justices of appeal in medico-legal trials. Such appointments have been urged by Sir Spencer Wells, Dr. Theodore Williams, and others, and will, if made, considerably strengthen the hands of justice.

HOSPITAL SUNDAY FUND.

THE sum received on behalf of this fund up to noon on the 10th inst. was, in round numbers, £32,000. Amongst the amounts paid in during the last few days is a collection of about £130 made at St. John's, Wilton-road, and the sum contributed at St. Stephen's, South Kensington.

THE Manchester pharmacists have, we understand, sent up very strong representations in favour of obtaining some special representation for their class upon the Committee of the Pharmacopœia to be established under the Medical Bill.

THE universities of Prague and Gratz have each recently established chairs for Hygiene.

Digitized by Google

A CORRESPONDENT at Cairo writes:—During the month of June there have been a few cases unofficially reported of vomiting and diarrhœa at Damietta, where it will be remembered the cholera of 1883 first appeared on June 22nd. The month's official return gives only seven slight cases of the character of gastro-enteritis, none of which proved fatal. Of these seven, diarrhœa was the chief symptom in three, vomiting in three, and in the remaining case the disease took a dysenteric form. It is satisfactory also to note that the mortality is below the average. And in this respect Damietta compares favourably with Cairo, where to-day the mortality reaches sixty-one, including ten cases of dysentery, six of typhoid fever, one of diarrhœa, two of "gastric fever," and seventeen of gastro-enteritis among children—that is, thirty-six of sixty-one cases, or 59 per cent., are of intestinal disease. In quoting statistics in Egypt, it is always necessary to remember that they are compiled by officials who are mostly ignorant of medicine, on information given by reluctant friends, for it is quite an exception for a sick person of the poorest class to be seen during life by any qualified medical attendant.

THE Mysore medical establishment is to be reorganised (says the *Indian Medical Gazette*), so as to allow of the subordinate staff becoming, in time, entirely composed of natives of Mysore who have passed the Madras M.B. or the L.M.S. Examination of Madras or Bombay. These will be under the supervision of two European officers, one of whom, a member of the Covenanted service, will be head of the Local Medical Department and chief medical adviser to the Mysore Government, and the second, who may be either a junior member of the Covenanted service, or a man selected from the profession in England, will have charge of all medical duties in Mysore.

MR. G. A. WALKER, M.R.C.S., L.S.A., died on the 6th inst. at Barmouth, North Wales, where he had lived in retirement for many years. Deceased played a prominent part in the agitation for the abolition of intramural interments, and in 1840 gave evidence before a Select Committee on the Health of Towns of the House of Commons respecting the sanitary condition of London and its graveyards. He was the author of "Gatherings from Graveyards," "The Graveyards of London," "Interments and Disinterments," and other works.

THE death occurred last week at Southsea of Mr. Abmnty Irwin, R.N., C.B., late Inspector-General of Her Majesty's Hospitals and Fleets. The deceased became a licentiate of the Royal College of Surgeons in Ireland in 1850, Hon. M.D. of Dublin in 1881, and was in 1874 nominated a Companion of the Order of the Bath (Military Division).

DR. GEORGE HARE PHILIPSON will deliver the Bradshawe Lecture at the Royal College of Physicians of London on Monday, August 18th, at four o'clock. Subject: "Pathological Relations of the Absorbent System."

DR. ARTHUR GAMGEE, F.R.S., has been appointed Fullerian Professor of Physiology of the Royal Institution for three years.

A CASE of meningocele starting at the root of the nose, and hanging down as far as the cheeks, was shown by M. Valtin at a recent meeting of the Société de Chirurgie.

THE Annual Report by Dr. King, of the Royal Botanic Gardens, Calcutta, for the year 1883-84 shows that the establishment is in a flourishing state.

SURGEON-MAJOR LONGMORE has been elected Foreign Corresponding Member of the Académie de Médecine.

DR. TOMMASI-CRUDELI ON CHOLERA.

ON the 30th ult., before the Accademia Petrarca of Arezzo, Dr. Tommasi-Crudeli, whose researches on the bacillus malariæ form a distinct advance in the etiology of intermittent fever, read a paper entitled "Cosa si può fare in tempo di Cholera?" ("What may be done in Cholera-time?") After tracing the history of the three great cholera epidemics that have visited Europe, he remarked that the disease was always an importation, never acclimatised like small-pox; and he defined it as a "contagio-miasma, a morbigenous germ, proceeding from a diseased human body, which never diffuses itself epidemically, except when the excretions containing it find in the soil conditions favourable to its multiplication."

THE CHOLERA GERM AND ITS DISCOVERER.

Filippo Pacini, of Florence, who died just a year ago (*vide* THE LANCET, July 21st, 1883), in 1854 was the first to recognise the cause of cholera in a microscopic organism, which Dr. Tommasi-Crudeli in 1882 classified among the schizomyceti (*σχίζω*, divide; and *μύκης*, fungus), or germs which multiply by simple division. This organism, according to Pacini, attacked the mucous membrane of the intestine; but his doctrine was ridiculed or disregarded till the other day, when the German Commission, investigating the specific cause of cholera in Egypt and in its native seat, the delta of the Ganges, came to the conclusion already arrived at by the Tuscan pathologist. Not only in the soil where fæcal dejections of cholera patients have found their way, but in the bed-linen fouled by these dejections and washed without disinfectants, may the cholera germ multiply. Pacini saw this as long ago as 1855, when, in a Tuscan township where cholera had raged in 1855, a poor woman having opened a chest of linen left to her by her mistress, who had died of the disease, was herself attacked and killed by cholera, which had been absent from the place a full twelvemonth.

LOCAL PREDISPOSITION TO CHOLERA.

The cholera germ imported by patients or their infected clothes becomes epidemic only in countries presenting conditions favourable to its development. This development does not happen everywhere in the same mode, and in certain places it does not happen at all. At Lyons, for example, a very large city on the road from Marseilles to Paris, in both of which the cholera raged, it never took root, although patients went to it from Paris and Marseilles to die. There are other places which are heavily visited on every occasion of the arrival of cholera from the East. Palermo is one of these, and presents a very grave "local predisposition." This predisposition, moreover, may be *intermittent*. At Florence the epidemic was slight in 1854, very severe in 1855. In 1867, knowing that cholera had not yet appeared there, crowds of people, many of them with the seeds of the malady in them, came to Florence, which by that time had become the capital of Italy; but, notwithstanding this immigration, cholera took no root in Florence on that occasion. When the disease has entered a country, we cannot say whether it will take firm hold or not. We only know that its spread may be favoured by four conditions: 1. Porosity of the soil in which choleraic dejections have been allowed to penetrate. 2. Oscillations of the underground waters by which the cholera miasm which has developed in the soil may reach the respirable atmosphere. 3. The accumulation of fæcal matters or of organic detritus infected by the germ. 4. The facilities offered to the diffusion of the germs in the drains, in the soil, in the air of the locality, and in the drinking water. Cholera, it should be added, has a mean incubation period of eight days before it declares itself in the organism.

FUTILITY OF SANITARY CORDONS.

Dr. Tommasi-Crudeli does not believe in sanitary cordons. They are as little able to keep cholera out of a province as custom-houses are to prevent smuggling. In Sicily, in 1837, some communes kept themselves isolated from contact with cholera-visited towns by planting loaded cannon round their suburbs; and in 1867 the same military tactics on the Alban Hills prevented the cholera-stricken Albans from communicating the malady to Castel Gandolfo, or Aviccia. But in

Digitized by Google

more civilised countries this remedy would be worse than the disease. Besides, the sanitary cordon tends to create a false security, and leads to neglect of hygienic duty, official and private. Quarantine afloat he has more belief in, if properly carried out, with due regard to the incubation period of cholera (eight days). But the sheet-anchor of the prevention of cholera is the exclusion from the dwelling-house and its inmates of the cholera germ. His counsels in this regard are similar to those of the English sanitary authorities—if possible a little more stringent as to the washing with disinfectants of all linen, whether visibly fouled or not with fæcal matter. As to prescribing a diet different from what suits the individual in ordinary health, he ridicules the notion. Let the food and drink be good and generous, the clothing warm (silk or flannel next the skin), and the spirits cheerful. The fear which at once dictates and maintains exceptional modes of living simply invites the onset of the disease. The resisting power of the community to cholera increases with each successive visitation. On its first appearance it made most victims; on the second invasion it found the weaker subjects already killed off, and the survivors better fitted to withstand it; so with the third visitation, and, as far as we can at present judge, with the fourth. "The morbigenous power of the cholera germ," says Dr. Tommasi-Cradeli, "is not attenuated, it only finds a smaller number of persons vulnerable." Other means of augmenting resistance to cholera have not been found. Last year Dr. Burcq suggested small doses of copper as a prophylactic, and all the French Commissioners in Egypt tried the drug, with the following result:—"At the close of the epidemic in Alexandria one day there was but one death from cholera, and that was Dr. Thuillier, the head of the Commission!"

THE INTERNATIONAL HEALTH EXHIBITION.

Group 1.—Food (continued).

We must begin by correcting one or two errors and omissions which seem important. Messrs. Savory and Moore's condensed peptonised milk is peptonised by pancreatine, and is therefore distinct in character from Mr. Darby's well-known and most powerful fluid meat. Messrs. Peek, Frean, and Co. draw our attention to another novelty, in addition to the valuable "health biscuit" which we noticed. This is the "café biscuit"—a brown, crisp, and very light biscuit, of delicate flavour.

Although the more familiar vintages are for the most part unrepresented in the present Exhibition, the wines collected in the South Gallery are interesting precisely because so many of them are unfamiliar. Of late years many countries have been striving hard to upset the supremacy which Spain, Portugal, France, and the Rhineland have so long enjoyed in England; and it is satisfactory to find that every year the strife becomes more successful. Austria, Italy, and Greece, countries which have produced good wine from time immemorial, seem at last to have convinced England of the fact; and our own colonies, Australia and the Cape, have taken an honourable part in the rivalry. The colonists have had the harder task, for they have had in a few years to learn the methods of growth and manufacture, which in older countries have been the work of ages. The chief exhibitors of Australian wine are Messrs. P. B. Burgoyne and Co., the Australian Wine Company, and the Colonial Wine Company. From time to time the steady improvement of these wines has been recorded in our pages. Many of these are now really excellent, and are beginning to be kept, as a matter of course, in London clubs. It is almost invidious to pick out one for praise, but we think that the Australian "Hermitage," red and white, ought to be more generally known. The Colonial Wine Company exhibit, in addition, red "Carbinets" from California and red "Shiraz" from the Lebanon. The last is an interesting modern revival of what is probably one of the oldest vintages in existence. To see it side by side with wine from Australia and California suggests many thoughts.

The wines of Austria are well represented by the administration of the Weinlaube and the well-known firm of Max Greger (Limited). The "Weinlaube" is a pretty arbour attended by a Dalmatian peasant girl in national costume. The "Austria-blume" and several other characteristic wines are exhibited within it, and there are also some interesting specimens and drawings illustrative of wine making and the ravages of the phylloxera. Mr. Max Greger has been so successful in introducing the wines of Hungary, that nowadays they scarcely require description. "The shareholder's Carlowitz" is particularly recommended by the Company. Mr. E. Vitali has collected in a pretty case (No. 147) some of the best wines of Italy. We have before now analysed and reported on some of these wines, and have found ourselves able to praise them cordially. At present we need only notice the remarkably pretty wickered baskets which adorn the case. Messrs. F. T. Denyer and Co. have a large collection of wines and spirits. The sherries of Sanlucar, including the well-known Manzanilla, occupy a prominent and well-deserved position in the list. The chief peculiarity in the exhibit of Messrs. Stallard and Co. (No. 162) is the old, highly-flavoured, and somewhat luscious white port, made from the white grapes of Oporto. And, finally, we must not omit Messrs. J. Christmas and Co. (No. 129), whose English wines—orange, lemon, ginger, gooseberry, and even champagne, made from real grapes—are good and, we believe, wholesome beverages. Mr. Grant's morella cherry brandy, orange and ginger cognac, and non-alcoholic sparkling morella, also deserve notice, as do the excellent lime-juice preparations of Messrs. Rose and Co. and Messrs. Feltoe and Sons.

There is little to remark about the spirits exhibited. The present popularity of Scotch whisky is abundantly illustrated—a popularity for which it is impossible fully to account, since Irish whisky can hardly be said to be on the whole inferior. We presume the consumption of gin remains much as it was, but rum is seldom drunk except by seafaring men, and brandy is now chiefly used as a liqueur with coffee. The differences between Scotch whiskies seem due chiefly to differences in blending, an art in which great skill is possible. We will not pretend to compare Glen Urquhart, Glencoe, Glenrosa, "challenge," Roderic Dhu, or the other whiskies exhibited in Class 4, for the task would be impossible without analysis. Messrs. Wilson and Parker have introduced some trace of novelty by marking their whiskies according to age with one, two, or three stars, as is done with brandies.

Very few brewers appear in the present Exhibition. We find on cases in the South Gallery the well-known names of Ind, Coope, and Co., Salt and Co., H. Lovibond and Son, Collier Brothers, and Stansfeld and Co., but Barclay, Meux, Bass, Allsopp, and a large majority of the other great English brewers are unrepresented. We cannot regret their absence, for English brewing and English beer are too well known to require illustration. But the production in England of the German lager beer is still a novelty, and is, moreover, an important industrial achievement. Lager beer is one of the most successful of the many foreign invasions to which in recent times we have been exposed, and considering its lightness and excellence we are glad to find its popularity increasing so rapidly. Until lately the whole of it was imported, but a German company styling itself the Austro-Bavarian Lager Beer Brewery commenced in 1881 at Tottenham the manufacture of several varieties of beers substantially identical with those brewed in Germany. They are all brewed on the German system—that is, the fermentation is carried on at a very low temperature, much of the yeast sinking instead of rising during the process. The four varieties sold are "Tottenham Lager," "Munich," "Bock," and "Pilsen." The last of these is a light table ale, the second and third are akin to porter and stout, but to judge from the analysis submitted to us all have an alcoholic strength not greater than 4½ per cent. by weight. The peculiar flavour, compared by some to garlic and by others to curry, is, we believe, generated in the manufacture, and is liked by those who are used to it. When the beer is intended for exportation or storage, it is "Pasteurised" by exposure to a temperature of 135° F., or thereabouts, after which it will, it is said, keep good in bottle for a twelvemonth. For draught it is aerated by a force pump, which brings it to the tap; and in hot weather it is cooled down to a temperature which renders it very refreshing. The case of Messrs. Gillman and Spencer (No. 157) deserves more than a passing notice on account of the novelty and scientific interest of the manufactures represented in it. *Pale*, may shortly be described as the gelatinisation of grain for use with malt in brewing. Grain of various kinds, but particularly rice, which appears best for

Digitized by Google

the purpose, is, after decortication, submitted to the action of super-heated steam, whereby the starch is gelatinised and brought into a fit state for the action of diastase. Some curious changes take place, and the diastasic power of the grain itself is said to be increased by the operation, so that it is to a certain extent malted. Before mashing, about 25 per cent. of "gelatinised rice-malt" is mixed with the ordinary malt, after which the brewing operations go on as usual. So far from this addition being an adulteration, it is claimed on definite scientific grounds as an important improvement in brewing, and it has been adopted already by many of the principal brewers. The nitrogenous constituents are present in barley malt in greater quantity than is required for the growth of the yeast cells, and the excess encourages the development of other organisms which spoil the beer. Such organisms are constantly found in malt. It appears, moreover, that the soluble albuminoids of barley malt have increased of late years, so that much difficulty has sometimes been found in getting beer to keep. Now rice contains a smaller proportion of soluble albuminoids than any other grain, and its addition to the mash therefore dilutes, so to speak, the nitrogen, and thus hinders the development of disease germs. Beer brewed on this system ought to keep bright better than other beer, and it is said that it actually does so, and is less likely to disagree with those who drink it.

Since Byron, in "Don Juan," commended the virtues of soda water, an enormous trade in artificially aerated waters has arisen. We suppose the so-called soda water is the most extensively used, but lemonade and the different varieties of ginger beer are also consumed in enormous quantities. We have on various occasions drawn attention to the carelessness with which the manufacture is often carried on, and to the grave risks introduced by the too frequent use of impure water, or of leaden vessels. The best makers now bestow the most studious care on every detail. Some of them employ distilled water, which gives of course absolute security as to organic matter, but which has sometimes a smoky taste somewhat hard to overcome. With a good water-supply, and proper precautions, distilled water is not essential. We find in Class 4 many exhibits of artificial aerated waters. Several of the exhibitors, notably Messrs. Packham and Co. and the Salutaris Company, use distilled water, a fact which we have verified by analysis. Messrs. May, Davis, and Co. use what they describe as purified, or "defecated" water. The last term is by no means a happy one. The manufacture of artificial mineral waters, in which the natural waters of England and the Continent are imitated, has received remarkable development of late. The current belief is that the artificial are inferior in efficiency to the natural waters. We confess that we can see no rational basis for the belief, and without venturing to dogmatise on what is still a moot point, are inclined to think that the observed differences may have arisen from imperfect knowledge and skill in the manufacturer. Many firms exhibit such artificial waters. The British and Foreign Mineral Water Company of Glasgow have sent us samples of several, including the well-known Selters, Vichy, St. Galmier, Hunyadi Janos, Carlsbad, Homburg, and Kissingen, which, in taste at any rate, are good imitations of the natural waters. The same company exhibit specimens of all the chemicals and a model of the tin-lined apparatus used in their manufacture.

Other exhibitors in this department are Messrs. T. Talbot and Co., of Gloucester and Monmouth; Messrs. W. Corry and Co., Belfast; Messrs. Cantrell and Cochrane, of Dublin and Belfast; and Messrs. J. Schweppe and Co., Pitt and Co., and Mr. H. D. Rawlings, of London. Messrs. Schweppe and Co. have a pavilion in the grounds, which at our last visit was unfinished.

PRACTICAL DIETETICS: A CHINESE LUNCHEON.

THE entertainment given on the 3rd inst. by the Chinese Commission to the Executive Council of the Exhibition is worthy of record as a decided novelty. The guests assembled at 1.30 P.M. in a picturesque cool kiosk overlooking the gardens. Decorated latticework, artificial flowers, painting and gilding combined with the soft air that had free access to the dining-room were certainly in striking contrast to the grimy stuffiness of the average London restaurant. Aloft, in a minstrels' gallery, were five Chinamen, pig-tailed, swarthy, and terrible, seated before an assortment of instruments unfamiliar to European eyes: quaint kettle-drums, tom-toms, fiddles of a kind, and bag-pipes of a sort, the minstrels resting, plying the fan, and occasionally refreshing the inner minstrel with something from a tea-pot.

The conventional waiters, some German and some English, bustling and perspiring, waiter-like, served as a capital foil to their Celestial colleagues, blue-robed, impassive, spotless, intent on the work of the instant and softly gliding in shoes of white embroidery soled with an inch of felt. The table-gear was European save the chop-sticks and the long-handled spoon which was placed to the right of every guest. Thus housed, attended, and furnished, we opened the attack on the *menu* of some twenty-five items.

Some shreds of gelatine in a saucer were followed by another saucer containing a dab of quaint pickle, highly decorative, piquant, queer, and very mixed. Following some sausage and olives came the first real excitement, "bird's-nest soup," which caused every guest's attention to be intently directed to the contents of the porcelain cup in front of him, and one after another we stooped to sip this greatest of luxuries, when suddenly Bang—whoop—smash—yah! We all started back with thoughts of dynamite. Thank goodness it was but the minstrels who had begun the Chinese national air, the first two lines of which done into English are—

> "Great Son of Heaven, thy glories shine,
> Reflected in thy land divine."

Never were sound and sense more widely apart than in this musical composition. The English paraphrase breathes forth a pious content, a sense of peace, a feeling of calm joy. The music to our ears seemed a mixture of the 5th of November (with an undue number of erratic squibs) and a railway accident; and the thwack of the high-pitched drums went through and through one. Eventually this musical tornado blew itself out, and we returned to the "bird's-nest soup," which proved to be amber-coloured, glutinous, savoury, and decidedly good. The "bird's-nest soup" was followed by a preparation of almonds, which resembled nothing so much as a cup of arrowroot, and a guest near us expressed an opinion that it ought to be eaten with the feet in hot-water and the nose tallowed. After a snippet of sole and an oddment of salmon, each on a quaint little saucer, we were refreshed with hot Shaoshing wine from a teapot. This is the only alcoholic drink in China, and is made from rice. It reminded us of something in the Pharmacopœia, but before we had made up our mind whether that something had emetic, purgative, or expectorant qualities, it was gone. The minstrels now treated us to a chorus with bagpipes, as though intent on inducing stomach-ache by sympathy of sounds and as a prelude to the Timbale *bêche de mer*, a preparation made from the holothuria, or sea-slug. This proved to be very good, and not unlike turtle; and as there is an abundance of holothuria on some parts of our coasts, it is not improbable that we may follow the lead of the Chinese, and that it may some day be found in the English market. We saw the raw material, which was shrunken like dried turtle, but plims prodigiously in the course of cooking. A mouthful of quail, a spoonful of curried mutton (excellent), lotus seeds, sunflower seeds, melon seeds, appropriate music, more hot wine, now followed in quick succession, and then came shark's fin with rice—this dish in colour and taste reminding us of bouillabaisse. Pigeons, punch jelly, quaint biscuits, and sweetmeats now came, and the tom-toms bursting into the familiar strains of "God save the Queen," very creditably performed, told us that the *menu* was accomplished. And so it was, with the exception of the final cup of imperial tea, which is worth eight shillings a pound in Pekin. The leaves at the bottom of the cup were pale in colour and apparently had not been rolled, and we were informed that this tea is sun-dried; the colour was very pale, the aroma most delicious, and the flavour delicate. Thus refreshed and restored, we passed into the Gardens, where a cigar and a concord of sweet sounds assisted the digestion of this strange mixture of Celestial eates.

ROYAL SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS.—The sixtieth annual meeting of this Society was held on the 7th inst. From the report which was read it appears that during last year there were 4618 convictions at the instance of the Society, an increase of 137 on the preceding year, and the accounts showed a balance of £222. The Society's gold medals, given by the Queen, were awarded to Dr. Fleming and Prof. Prichard.

A MEMORIAL TO THE LATE DUKE OF ALBANY.

LORD SHAFTESBURY writes to *The Times*:—"Your columns recently contained a proposal reprinted from THE LANCET that a portion of the new building now being erected for the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, should be made a memorial to the late Duke of Albany, whose interest in the undertaking had been freely manifested. This proposal has been submitted to the Queen, and Her Majesty has been pleased to sanction its adoption. There must be many desirous to do honour to the memory of the esteemed Prince, whose short life was in so large a measure devoted to works of general utility, and in the valuable institution I write of the public sentiment will perceive an enduring memorial, and such as he would have valued most. I have gladly acceded to a request to preside over a meeting in Willis's Rooms on Monday next, the 14th inst., when the Queen's gracious communication will be read and resolutions will be proposed. The cost of the new hospital, which will be about £60,000, exclusive of site, is all provided for but a balance of £12,500, and one of the objects of the meeting is to aid the board in the collection of this sum. The treasurer, the Hon. H. D. Ryder (Messrs. Coutts) or the secretary, at 36, Queen-square, will gladly receive contributions from any willing to help the completion of the important work so advantageously inaugurated by the late Prince, but which can be finished only as a posthumous tribute to his worth."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5554 births and 3279 deaths were registered during the week ending the 5th inst. The annual death-rate in these towns, which had been so low as 18·7 and 19·2 per 1000 in the two preceding weeks, further rose last week to 19·5. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·8 per 1000, against 20·9 and 21·5 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 12·5 in Derby, 13·4 in Brighton, and 14·3 in Bristol. The rates in the other towns ranged upwards to 23·7 in Sunderland, 23·8 in Oldham, 25·6 in Plymouth, and 26·1 in Huddersfield. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 572, and showed a further increase upon the numbers in recent weeks, owing to the greater mortality from diarrhœa; they included 175 from diarrhœa, 126 from measles, 103 from whooping-cough, 61 from scarlet fever, 46 from "fever" (principally enteric), 36 from small-pox, and 25 from diphtheria. No death from any of these diseases was registered last week in Derby, whereas they caused the highest death-rates in Leicester, Liverpool, and Plymouth. The greatest mortality from diarrhœa occurred last week in Preston, Plymouth, and Leicester; from measles in Blackburn, Liverpool, Plymouth, and Wolverhampton; from whooping-cough in Leicester and Sunderland; and from scarlet fever in Cardiff and Sheffield. Of the 25 deaths from diphtheria in the twenty-eight towns 15 occurred in London, 3 in Portsmouth, and 2 both in Bristol and in Liverpool. Small-pox caused 34 deaths in London and its outer ring of suburban districts, exclusive of 11 London cases registered in the metropolitan asylum hospitals situated outside Registration London; also 3 in Liverpool, 2 in Sheffield, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals, situated in and around London, which had been 1316 and 1290 on the two preceding Saturdays, again rose to 1368 at the end of last week; the number of new cases admitted to these hospitals, which had been 354 and 260 in the two previous weeks, were 266 last week. The Highgate Small-pox Hospital contained 81 patients on Saturday last, against 90 and 83 on the two previous Saturdays; the new cases admitted were 20 last week, against 22 and 11 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the nine preceding weeks from 360 to 218, rose last week to 231, and exceeded the corrected weekly average by 30. The causes of 71, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Bristol, Portsmouth, Salford, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Birkenhead, Oldham, Bradford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the four preceding weeks from 23·3 to 20·6 per 1000, rose to 21·8 during the week ending the 5th inst., and exceeded by 2·3 per 1000 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·9 and 15·1 in Greenock and Perth, to 23·2 in Dundee and Paisley, and 25·8 in Glasgow. The 526 deaths in the eight towns included 32 which were referred to whooping-cough, 13 to diarrhœal diseases, 10 to measles, 10 to diphtheria, 7 to "fever," 6 to scarlet fever, and not one to small-pox; in all 78 deaths resulted from these principal zymotic diseases, against 83 and 86 in the two preceding weeks. These 78 deaths were equal to an annual rate of 3·2 per 1000, which was slightly below the mean rate from the same diseases in the twenty-eight English towns. The 32 deaths from whooping-cough corresponded with the number in the previous week, and included 22 in Glasgow and 6 in Edinburgh. The 13 fatal cases of diarrhœa slightly exceeded the low number in the corresponding week of last year. The deaths from measles, which had been 14 and 15 in the two preceding weeks, declined to 10, of which 6 occurred in Glasgow. The 10 fatal cases of diphtheria exceeded the numbers in recent weeks, and included 5 in Glasgow, 2 in Dundee, and 2 in Edinburgh. The 7 deaths from "fever" showed a decline of 3 from the number in the preceding week, 4 were returned in Edinburgh, and 2 in Glasgow, where 4 of the 6 deaths from scarlet fever were also recorded. The deaths referred to acute diseases of the respiratory organs in the eight towns, which in the two previous weeks had been 74 and 85, were last week 83, and were considerably below the number returned in the corresponding week of last year. The causes of 104, or nearly 20 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 21·7, 27·1, and 28·2 per 1000 in the three preceding weeks, declined to 21·0 in the week ending the 5th inst. During the thirteen weeks of last quarter the death-rate in the city averaged 26·5 per 1000, whereas the rate during the same period did not exceed 19·9 in London and 21·6 in Edinburgh. The 141 deaths in Dublin last week showed a decline of no fewer than 49 upon the number in the previous week; they included 18 that were referred to the principal zymotic diseases, against 10, 15 and 14 in the three preceding weeks; 10 resulted from scarlet fever, 3 from diarrhœa, 2 from diphtheria, 2 from "fever" (typhus, enteric, or simple), 1 from whooping-cough, and not one either from small-pox or measles. These 18 deaths were equal to an annual rate of 2·7 per 1000, the rate from the same diseases being 4·0 in London and 3·6 in Edinburgh. The 10 deaths from scarlet fever in Dublin last week showed a marked increase upon the numbers returned in recent weeks, while those from "fever" were fewer than in any recent week. The 3 deaths attributed to diarrhœa corresponded with the number in the previous week. Three inquest cases were registered, and only one death resulted from violence; 49 deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a marked decline from the numbers returned in previous weeks. The causes of 14, or 10 per cent., of the deaths registered during the week were not certified.

MISS WARDELL'S CONVALESCENT HOME FOR SCARLET FEVER.—The Princess of Wales, the Patroness, has consented to open the Home at Brockley Hill, Stanmore, on Monday July 14th. A sale of work will be held at the Home on the day of the opening and following days.

"Audi alteram partem."

"THE PATENT MEDICINES STAMP ACT."

To the Editor of THE LANCET.

SIR,—In your leading article contained in the issue of July 5th you animadvert upon the present condition of the law which regulates the sale of patent medicines. Now this subject is one of such paramount importance, alike to the profession at large and to the public, that I may be pardoned for bringing forward some other aspects involved in the existing state of affairs. You mention that the Act of 1812, which by the way was passed to enlarge and amend a former statute, is still the guide and mentor for the authorities at Somerset House. In the schedule appended to this Act is a long list of nostrums, many of which are now simply names, while the ruck of the present patent medicines come under the Act by virtue of the words that any preparation is "held out or recommended to the public," by advertisement or otherwise, "as nostrums or proprietary medicines, or as specifics, or as beneficial to the prevention, cure, or relief of any distemper, malady, ailment, disorder, or complaint." And further, this Act, which you stigmatise as peculiar and incomprehensible, includes among its schedulel articles "foreign medicines of all kinds, except drugs." But the Act was passed eleven years before that eventful Oct. 5th, when No. 1 of THE LANCET appeared, and at a time when pharmacy was primitive, if not savage, and the profession were more apt at phlebotomising than conversant with the study of the physiological action of drugs. During the past three-quarters of a century this Act has lain in the limitless limbo of unintelligible statutes passed for the guidance of the people and the pecuniary aggrandisement of the lawyers; but at the present time the whole reading, scope, and, I think we may say, purport, of the Act have been altered, its spirit quashed, and its letter raised into what may prove a most disastrous prominence. When we consider the reckless and unreasoning way in which the authorities have unearthed and contorted an effete enactment such as the Stamp Act of 1812, we may well review the situation and ask how long shall such things be? You, Sir, have drawn attention to the fact that, according to the modern interpretation of the Act, it has taken upon itself the form and semblance of an impudent "puff," whereof the patent medicine mongers have not been slow to avail themselves. But another issue has yet to be considered. As it would appear, Her Majesty's Commissioners possess a wide discretionary power in the matter of selecting what constitutes a "specific" or a drug; and even the seemingly simple problem, "What is a foreign medicine?" admits, according to Her Majesty's Commissioners, of many and startling solutions. It is to the manifest injustice, and we may add, in Carlyle's English, "unreason," of this discretionary power indiscreetly administered that I wish to draw attention. Not only are the principles of free trade glaringly violated and protective policy flaunted, but medicines which are undoubtedly proprietary are privileged; while similar compounds, because they emanate from foreign warehouses, and are pushed with the vigour which characterises the manufacturing chemist of to-day, are condemned to pay toll. The Commissioners are strictly within their legal right when they assert that their province lies, not in rectifying a stupid and effete law, but in carrying the same into effect. When, however, such wide discretionary power is left in their hands, it is strange that they take no pains to ascertain whether their proceedings are in harmony with the knowledge or accepted usage of the day. To be gravely told that sulphate of quinine cannot be said to be a drug, as it is compounded of sulphuric acid and quinine, inclines one to push inquiry further, and to seek an example of a simple substance. We are told that a drug made up with a common vehicle into a suppository becomes a medicine which must be stamped. A well-known nostrum prescribed for asthma, proprietary to the ninetieth degree, escapes, because it "is neither a medicine taken internally nor applied externally." A princely fortune has been amassed by the proprietor of an agreeable laxative salt sold in powder; but this is not a patent medicine, we are told, and so eludes Her Majesty's Commissioners, because it is, so they tell us, a natural effervescing water.

I have cited a few examples out of a host, because such flagrant misdirection alike of common sense and justice must show the utter futility of anything short of a repeal of the law as it now stands and is now enacted. Let us glance at the upshot of the measures the Inland Revenue Commissioners are proposing: All medicines which have enjoyed a printed reputation in the treatment of any particular disease—for example, digitalis in disease of the mitral orifice,—all alkaloids, and practically all the less common remedies (seeing they are mostly imported) will become liable to be stamped; they will then be regarded by the intelligent British public as safe additions to the family medicine chest, and glonoin capsules will be as glibly spoken of and as disastrously used as are the present opium-dosed "soothing syrups" or "teething powders." Prescribing must cease, or be replaced by a *memoria technica* well stored with the names and addresses of those chemists who import or prepare the various alkaloids and preparations of an extra pharmacopœia. From whatever standpoint this matter is viewed it seems big with disaster, and fruitful of injustice and inconvenience.

I am, Sir, your obedient servant,

Gower-street, W., July, 1884. DUDLEY W. BUXTON, M.D.

To the Editor of THE LANCET.

SIR,—In reference to the question of the stamp duties on patent medicines, some interesting comparisons arise with respect to the custom in other countries and their consequences. In France, for instance, there is no tax of any kind on nostrums or proprietary medicines; the law carefully avoids doing anything which can be construed to authorise or approve of their sale; indeed, nostrums as such are absolutely forbidden until, by an analysis conducted by a state official, it can be shown that they contain nothing which might prove dangerous in the hands of the most inexperienced. The regulations relating to the sale of poisons in France are very strict, and the law prohibits, except under an order from a doctor, the sale of any medicine, proprietary or not, which contains other than harmless drugs. The result is materially to lessen the risk of the imprudent employment of potent remedies, while great difficulties are placed in the way of individuals disposed to indulge a morbid taste for narcotics, whether in the form of opium, morphia, or chloral. In England, apart from the extraordinary facilities afforded for the sale of these substances, the myriad quack mixtures offer a ready loophole of escape, both morally and legally, to those who desire to employ drugs, the use of which, except under medical advice, is fraught with so much risk and danger.

The stamp in England lends itself admirably, or disastrously, to the purposes of advertisement. I have before me a large collection of such advertisements, marvels of ingenuity in their way, where the stamp is made to convey the impression—and this in no ambiguous terms—that Her Majesty's Government have examined the medicine enclosed, and certify not only to its genuineness, but also that it possesses the qualities which the proprietor of the medicine has thought fit to ascribe to his compound. This is no fictitious—still less a factitious—objection. The plausible manner in which these advertisements are worded is calculated to mislead all but those who are in a position to appreciate their value, and it is a fact familiar to most of us that people attach much the same importance to the stamp as they would to the Hall mark on silver plate. That the fictitious importance so conferred—a thing, by the way, which excites a good deal of ridicule abroad—is beneficial to the proprietors of these preparations is evidenced by the fact that they are strongly opposed to the abolition of the tax; nor, indeed, is this to be wondered at, as the cost does not fall on their shoulders, and the benefit to them is only too apparent.

It is most desirable that a tax so hurtful in its effects should be at once abolished, and that henceforth, or until further legislation on the sale of poisons stops their unauthorised and indiscriminate use altogether, they will be left to rely for prestige on the specious wording of their vendors, and cease to be invested with the halo of State recognition. I am, Sir, your obedient servant,

ALFRED S. GUBB.

Westminster Hospital, Broad Sanctuary, S.W., July, 1884.

FURTHER DISCOVERY OF ROMAN REMAINS IN LINCOLN.

To the Editor of THE LANCET.

SIR,—Permit me to supplement the letter on the discovery of Roman remains in Lincoln published in THE LANCET of June 14th.

The workmen, a few days ago, whilst extending the digging out of the foundations of the old house at the angle formed by Bailgate and Eastgate preparatory to the building of a new one, came upon a quaint-looking Roman arch, six or eight feet north-east of the sarcophagus or small chamber in which, as stated in my former letter, the ten urns were discovered. This arch or door-way, which had necessarily to be removed, formed a right angle with the sarcophagus, and was about six feet high and two feet wide Like the large Roman arch at the upper or northern end of Bailgate, it had no keystone, the formation of all the stones in the arch obviating the necessity for one. Leading from the door of the sarcophagus to the arch was a semicircular path made of concrete. This path, after passing through the arch, dipped down two feet and a half to make the floor of a small room five feet square and seven feet high.

On Thursday morning, the 26th inst., the workmen, whilst in the act of taking down the arch, discovered a large urn, and on clearing away the rubbish out of the room found three or four more urns of large size. The urns previously discovered in the sarcophagus held from two to three quarts of fluid; those recently discovered, before they were damaged, would have held as many gallons. They were embedded in lime, had no lids, and all contained ashes of the dead, the ashes being covered over with charcoal. The small room in which these urns were found smelt most offensively, and on washing a fragment of one of the urns, a most disagreeable odour arising from the fragment was complained of. Putting the pieces of one of the urns together, I could see that it was somewhat globular in shape, with a large mouth, the rim of the mouth being neatly and elegantly curved outward to the extent of nearly two inches. The colour of the urn examined is black, and it is a good, although a coarse, specimen of the old Roman ware called "Upchurch." The fragments of this urn presented an appearance which leads me to believe that the vessel was twice "fired." It is therefore probable that after the dead had been burned in the ordinary way the remains were collected, placed in this large urn, and it and its contents were again subjected to the fire of the crematorium.

Mr. *Hibbitt*, the intelligent foreman of the works, is of opinion that the arch and the room recently discovered are of much older date than the sarcophagus and apartments previously discovered. Over these old Roman buildings a Norman edifice of some kind had been erected, and Mr. Hibbitt pointed out the differences between them. The building of the Romans was "splendid," and the workmen with difficulty pulled down the old walls. The building of the Normans was as different as possible. They made the "faces" of the walls even and smooth but the spaces between the faces they filled up with rubbish of any kind that came to hand, consequently their work fell to pieces when struck by the workmen.

The crematorium and the other buildings devoted to the final disposal of the dead seem to have stood in a north-westerly angle of an enclosure or outer courtyard, and this courtyard in all probability belonged to the beautiful villa discovered a year or two ago. The villa stood on one of the finest sites in the city, and was situated only fifty yards directly in front of and southward of the crematorium buildings. Although this place of sepulture may have been owned by successive Roman governors, still it does not appear to have been held sufficiently sacred to be isolated from the busy world about it. Not more than twelve or fourteen yards from it eastward was found, firmly and well puddled in the earth, a nine- or ten-gallon water-jar for the use of animals to drink from, and a neat drain was also found to convey away the water overflow of the jar. Still nearer to the sepulture buildings was a well in the centre of a large flat stone, four feet square, and well worn by the feet of those who went thither to draw water. Scattered about were large square tiles, having one side of the square curved round, as if intended to hold something. A packing-needle, of fine brass wire, was found with thread wound around it, and also a handsomely made leaden box, resembling very much the old-fashioned poor-box, with long shaft handle. The handle in this case was wanting, but the tapering socket is there, supported by neat brackets. In still closer proximity to the buildings was the ashbin, among the rubbish of which were found numerous oyster shells and broken pottery, sufficient to demonstrate that breakages occurred in those days as well as in these. I found the lower part of a flower-pot of Samian ware, having a hole in the bottom for the escape and admission of water in the same way as a flower-pot of the present day. The inverted saucer-like lid for vessels seemed to be very fashionable in those times. The Chelsea people and Orientals made similar lids for sugar-basins. I saw the spout of a jug of Castor ware of the same shape as some of the beautiful Dresden milk-jugs.

I am, Sir, very truly yours,

Lincoln, June 28th, 1884. WILLIAM O'NEILL, M.D.

"VACCINATION IN THE METROPOLIS."

To the Editor of THE LANCET.

SIR,—Under the above heading in last Saturday's LANCET you publish an article stating that the proposal which I made in the House of Commons the other day for the prevention of small-pox in the metropolis was, as you understood it, "to transfer from the boards of guardians to the thirty-nine sanitary authorities the administration of the Vaccination Acts." Permit me to say that I never suggested any such thing. Further on you add that I "demanded a more general use of lymph from the calf." That also is an entire mistake. What I advocated was a slight modification of existing machinery, which might be secured almost without legislation, and which would secure the prompt disinfection and revaccination of infected households as well as the prompt isolation of small-pox patients. The principles of the system I advocated have in Glasgow, where there is no calf lymph, reduced the death-rate from small-pox to less than one-fiftieth of what it stood at before that system was adopted, and to less than one-twenty-fifth of the present death-rate in the healthiest districts of London. As I showed, they could be adopted here without the slightest dislocation of existing machinery, and probably when the recrudescence of the epidemic next year has sufficiently aroused public indignation, the obvious administrative improvements which I suggested will be adopted. Till then I must console myself with the reflection that I have done all I could to avert any needless addition to the thousands of lives which in the metropolis have within the last ten years been deliberately sacrificed at the altar of Small-pox by the High Priest of Red-tape. I am, Sir, yours truly,

House of Commons, July 9th, 1884. CHARLES CAMERON.

DIAGNOSIS OF SMALL-POX.

To the Editor of THE LANCET.

SIR,—It is not very surprising that errors are not infrequently made in the diagnosis of small-pox, as it is a disease which rarely comes under the observation of general medical practitioners, except during epidemics, and is even then confined to certain localities to a great extent; but with care, and a knowledge of the medical literature on the subject, so far as it can be acquired without much difficulty or expenditure of time, serious errors may be avoided. However, a case illustrative of the grave consequences of a mistake in diagnosis has come under my notice, and I think it is of a nature worth the attention of medical men, especially while small-pox is rife in London. The facts as described by one of the family are these. The father was taken ill and died after a short illness, the immediate cause of death being hæmorrhage from one of the mucous tracts. There was no apparent small-pox eruption of the usual character, but very extensive petechial or hæmorrhagic colouration of the skin, described as "purple," lividity around the eyes, on the forehead, &c.—in fact, the characters of a severe case of hæmorrhagic small-pox. Seemingly the diagnosis was simple purpura, as the family were assured that there was nothing infectious. However, first two of the children, then the wife, and lastly a third member of his family, were attacked with small-pox, without any apparent history of infection from without, but fortunately in them the disease was of a milder type. If the diagnosis

Digitized by Google

had been correctly made in time, the spread of the disease might have been checked with the case of the father, as it was almost, if not quite, a fortnight before it showed itself in the other members of the family.

I am, Sir, yours obediently,

JAMES A. PHILIP,

July, 1884. Medical Officer, *Red Cross* Ambulance Steamer.

NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

CASE OF GASTROSTOMY.

I SAW to-day in the wards of the Newcastle Infirmary an interesting case in which the operation of gastrostomy had been successfully performed by Mr. Page. The patient was a stonemason, about forty-six years of age, and, except for being a heavy drinker, there was nothing to point to as a cause for the symptoms of dysphagia, which came on gradually, but became very urgent about the beginning of the present year. It is nearly a month since he was admitted to the infirmary, and fully three weeks since the operation. Mr. Page made an incision through the rectus muscle on the left side, and to this the stomach was secured by wire sutures, and opened three days later, the patient in the meantime being sustained by nutrient enemata and hypodermic injections. When the gastric fistula was fully formed he was fed through an elastic tube, and at the present time, although he is still being fed by the tube, he has recovered some power in swallowing, and has increased in weight four pounds since the operation. At the time of the operation he was harassed by a hectic cough, and this somewhat induced Mr. Page to make his opening through the rectum, the structure of the muscle acting in a valvular manner, and so preventing expulsion of the contents of the stomach during the act of coughing. The presence of the tube appeared to give the patient, who was able to walk about the ward, very little trouble. The case is doing well.

THE DWELLINGS OF THE POOR.

A conference convened by the Bishop of Durham has been held this week in Bishop Cosin's library, Palace-green, Durham, this week, having for its object the condition of the dwellings of the poor in the county of Durham. The meeting was a representative one, attended by medical officers of health and other members of our profession taking a direct interest in sanitation. A general sanitary aid committee was formed at the meeting.

REMARKABLE CASE OF EXCESSIVE DRINKING.

An inquest was held yesterday at Middleton, near Darlington, in which it was shown that a lady had died from excessive drinking, inducing epileptic convulsions, in one of which seizures she would appear to have been suffocated in her chair. From the evidence given, it was clear that she had been addicted to excessive drinking for about three years, and during that time she had drunk from two to three pints of whisky daily.

THE COPENHAGEN CONGRESS.

It might be mentioned, in view of the approaching meeting in the Danish capital, that one of our leading shipping firms here has notified its willingness to take all members of the profession from Newcastle quay to Copenhagen and back for the extremely low sum of thirty shillings. I hear on all sides of active preparations for the journey, although some are bent on crossing St. George's Channel as well as the Cattegat.

ACCIDENT TO DR. HEATH.

I regret to say that Dr. Heath, of our city, met with a serious accident yesterday while driving with a female patient and nurse in the neighbourhood of Chester-le-street. The horses bolted, the vehicle was upset, and the occupants were violently thrown out; Dr. Heath has several ribs fractured, while the females are also seriously injured.

Newcastle-on-Tyne, July 1st, 1884.

THE managing committee of the Warneford Hospital at Leamington have appointed Miss E. M. Swain, daughter of Professor Swain, of Queen's College, Birmingham, resident dispenser to the hospital.

PARIS.

(From our Paris Correspondent.)

THE CHOLERA EPIDEMIC.

THE meeting of the Academy of Medicine yesterday was looked forward to with great interest, as it was anticipated that Dr. Fauvel, in the face of evidence against him, would have made another declaration tending to modify that which he first made—namely, that the epidemic at Toulon was none other than sporadic cholera. Warm discussions would necessarily have followed; but Dr. Fauvel, acting on the wise adage, "a good retreat is better than a bad fight," made himself scarce, and instead of attending the meeting to defend his cause in person, he addressed a letter to the President of the Academy excusing himself, as from the shattered state of his health from over mental work, he was obliged to go to the country for at least a month to seek that rest which he could not obtain if he remained in Paris. In his letter, however, he still adheres with great tenacity to his former opinion, and states that, by whatever name the epidemic may be qualified, it is none other than the "cholera nostras," that is to say, engendered at Toulon, it will become extinct without extending beyond its present seat, where it will be so concentrated as to become the starting-point for an epidemic which will invade all France. There seems some contradiction in this assertion, but I give it as it appeared in Dr. Fauvel's published letter. Dr. Fauvel further states that the stray cases, more or less choleraic, and more or less numerous, met with at Marseilles will be extinguished with the end of the great heat, without having given rise to a veritable epidemic of Asiatic cholera. Dr. Rochard, who had just returned from Toulon, made his appearance at the Academy, and protested in rather strong terms against the assertions of Dr. Fauvel. I need not trouble your readers with his arguments, as he simply goes over the old ground. At the same time, he endeavours to prove that the present epidemic, which according to him is of the true Asiatic type, was not imported by the French ships coming from the East, but insinuates that the disease was brought over the Red Sea, which of course means that the English were the guilty party. Dr. Rochard then made some remarks on the treatment employed by medical men at Toulon. After having tried various remedies, the following is that now adopted. Hypodermic injections of ether in the stage of prostration, and atropine, also used hypodermically, to relieve the pain and cramps attending these cases. The inhalations of oxygen, which you have already referred to, have, according to Dr. Rochard, been attended with such favourable results as to encourage perseverance in them, particularly when the patients are plunged into a profound state of coma. Dr. Rochard observes that, whatever the treatment, the number of cases has been extraordinarily great, particularly in the navy, where the proportion of deaths was only one in five cases. As preventives, the principal remedies consist in sanitary measures, such as segregating the inhabitants, and thus preventing the crowded state of the town; with these measures the place should be thoroughly cleansed and disinfected: but he deprecates the ridiculous extent to which disinfection is being carried out, much to the annoyance of travellers, who are put to inconvenience by the unnecessary detention they are subjected to, and which, as Dr. Rochard himself admits, is perfectly ineffective. Dr. Koch, who is now at Toulon, where, it is said, he met with cold politeness by the medical staff of the hospitals, is now at work with his two young French colleagues of the cholera mission to Egypt, Drs. Strauss and Roux, who gave him a friendly reception, and it is to be hoped we shall soon know the result of their investigations. Meanwhile, Dr. Koch has declared that the disease before him is clearly Asiatic cholera. He does not believe that the germs are transported by the air, adding that the microbes are not transmissible, but by the human body, by the dejections, or by the wet linen containing these dejections. He is of opinion that after a few days, about eight, the infected linen does not contain any more dangerous microbes. In accord with the greater number of hygienists, he has no faith in simple external fumigations. A few stray cases have occurred in the provinces near Toulon, but with one or two exceptions they have turned out to be false alarms. The same thing happens daily in

Digitized by Google

Paris, and with the same results. Meanwhile, every precaution is being taken to prevent the incursion of the disease.

FRENCH JURORS AT THE INTERNATIONAL HEALTH EXHIBITION.

The following gentlemen have been designated to represent France among the jury of the International Exhibition of Hygiene now being held in London:—Professor Arnoult of Lille, Professor Brouardel, Dr. Gariel, Dr. Henry Guéneau de Mussy, Professor Layet of Bordeaux, Dr. Lionville Deputy, Dr. Napias, Dr. Proust, and Dr. Vallin.

Paris, July 8th, 1884.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—We understand that *thirty* appointments are offered for competition at the examinations in August next instead of *nineteen*, as previously advertised.

Surgeon-Major Augustus Frederick Elliot, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon Herbert Cotton has been placed upon temporary half-pay on account of ill-health.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon William J. Eames, to the *President*, additional, for temporary service at the Royal Victoria Yard; Surgeon Robert G. Bird to the *Achilles*; Surgeon John O'Callaghan, to the *Tyne*; Surgeon George W. F. Armstrong, to the *Belleisle*.

ARTILLERY VOLUNTEERS.—1st London (City of London): John Joseph Ardavon Vincent Constantine Raye, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Shropshire: Acting Surgeon John [illegible] resigns his appointment.

ROYAL COLLEGE OF SURGEONS.

At the quarterly meeting of the Council, held last Thursday, the [illegible] twenty elected members took their seats—namely, Mr. [illegible] Smith, George Lawson, A. E. Durham, Berkeley Hill, [illegible] Allingham. Mr. Cooper Forster was elected President of the College for the ensuing year, in the place of Mr. [illegible], and Messrs. Savory and Holmes were elected senior and junior Vice-Presidents respectively. In accepting the office of junior Vice-President, Mr. Holmes stated that he [illegible] it to be understood that he did not intend to accept the office of President, as he disapproved of the principle of election by rotation. Mr. C. Stewart was [illegible] admitted Conservator of the museum. The various committees were appointed, and the several professors and lecturers were elected. Messrs. Lund and [illegible] were elected Professors of Surgery and Pathology, and Messrs. Parker, Brailey, Stewart, Treves, and A. Hill Professors of Comparative Anatomy and Physiology. Mr. [illegible] was re-elected Lecturer on Anatomy and Physiology, and Mr. Stewart the Erasmus Wilson Lecturer. The motion of Sir Spencer Wells's motion—"That all conclusions of the Council be considered as in force [illegible] have been formally rescinded"—was not carried; the latter part—"That any existing resolutions which [illegible] on the Council be rescinded"—was by leave withdrawn. Sir Erasmus Wilson was nominated as a candidate for the honorary medal of the College, the ballot for which will take place at the next meeting of the Council.

MEDICAL ACT AMENDMENT BILL.

[illegible] going to press on Friday morning the Bill [illegible] attached, but is still on the list. Should there be no opposition, it is sure to pass; otherwise there is little chance of its becoming law this session. The passing of the Bill is to be obtained only [illegible] the adoption of Sir Lyon Playfair's amendment, [illegible] hardly be disappointed at the latter consenting that the amendment would have so seriously [illegible] value of the measure as to make it [illegible] little worth.

MEDICAL NOTES IN PARLIAMENT.

Sanitation in Clerkenwell.

THE President of the Local Government Board, in his speech on the second reading of the London Government Bill on Friday night in the House of Commons, declared that the insanitary condition of the parish of Clerkenwell rendered that district "a danger and a disgrace to the whole of the metropolis," and that the vestry which allowed it to remain in that condition was unfit to exercise the powers entrusted to it.

The Thames.

The Chairman of the Metropolitan Board of Works on Monday admitted to Mr. D. Grant that the state of the Thames at East Greenwich, in the neighbourhood of the sewage outfall, was offensive and dangerous to the public health. He said directions had been given for the liberal use of deodorising agents, but the difficulty had mainly arisen through the dry weather, there being but a small flow of upland water. Special instructions had been issued to the Board's engineer, who had full authority to take whatever measures were possible to mitigate the nuisance.

On Tuesday, in the debate on the London Government Bill, Mr. Boord, one of the members for Greenwich, reverted to the subject by way of complaint of the inefficiency of the Metropolitan Board.

Covent-garden.

Sir J. Hogg, in reply to Sir F. Milner on Monday, repudiated any responsibility on the part of the Metropolitan Board with regard to the foul condition of the streets in the neighbourhood of Covent-garden, but stated that he had called the attention of the Strand District Board to the matter.

The London Sewerage System.

On Tuesday, Mr. Russell informed Mr. Gourley that the Local Government Board had no legal control over the cleansing and flushing of the metropolitan sewers, which were under the jurisdiction of the local authorities.

The Cholera.

Replying to Mr. Gray, answers were respectively given by Mr. Russell and by Mr. Trevelyan to the effect that the necessity had not yet arisen for issuing special regulations under the Public Health Act, in view of the importation of cholera into England and Ireland. The sanitary authorities already possessed very large powers, and the exceptional provisions of Section 134 would be applied directly it became evident that this country was really threatened with the disease.

The Medical Bill.

During the week about a hundred petitions from various places throughout the kingdom have been presented in favour of Mr. Sclater Booth's amendment for the appointment of a Pharmacopœia Committee.

On Thursday evening, in making a general statement as to the course proposed to be taken by the Government, Mr. Gladstone said: "With regard to the Medical Act Amendment Bill, I do not give a final judgment, and upon this ground. In the first place, my noble friend the Lord President of the Council, and my right hon. friend the Vice-President, are, I believe, of opinion that they have very nearly arranged the principal contested points connected with the Bill. A short time would test that. It is also a Bill which has made considerable progress. It is now in Committee, with the mark of 'Progress' attached to it; and without interfering with the course of business, it is a Bill upon which we may easily ascertain at a later hour of the evening whether the House will proceed with it."

Vaccination.

In reply to Mr. Hopwood, Mr. Mundella stated that the Education Department had no power to sanction the examination of scholars in Board Schools for the purpose of ascertaining whether they had been vaccinated. The visit of some person (presumed to be in the employ of the local authorities of St. Pancras) on Wednesday last to the Henry-street School for this purpose had therefore not received the sanction of the department.

Digitized by Google

The Patent Medicines Bill.

Mr. Mundella replied to Mr. Warton that the Irish Government had not yet communicated their decision as to whether Ireland should be included in this measure, the fate of which was now dependent upon a higher authority than his. A good many things had happened since March 22nd, and possibly there were good reasons why the Bill had not been proceeded with.

A Parliamentary Nuisance.

In reply to Mr. James Lowther, Mr. Shaw Lefevre said he had received complaints from hon. members of a very offensive odour in the House of Commons, but he was satisfied it was not caused by any defect in the ventilating arrangements of the House. It proceeded from some outside cause, which he believed to be the Victoria-street sewer; but he would have no objection to a small committee investigating the matter. He had communicated with the Metropolitan Board on the subject.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 4th, 7th, 8th, and 9th inst.:—

Hugh A. Clarke, Liverpool; Edward E. Barret and H. G. Tandy, Charing-cross Hospital; Rupert W. Clayton and S. G. Vinter, St. Mary's Hospital; William S. Whitehead, Arthur B. Stevens, A. E. Gresham, and H. E. Whitehead, St. Bartholomew's Hospital; Robert H. M. Roberts, St. Thomas's Hospital; Bertie S. Johnson and Walter R. Garrould, University College; Henry T. Kelsall, G. E. Haslip, Charles E. Scudamore, Horace A. Debenham, Harold E. Owen, R. Hitchings, and J. F. Vincent, London Hospital; C. H. West, G. A. Wybourn, E. F. Gardner, C. A. Lumley, and S. Woodhams, Guy's Hospital; G. McNair, King's College; John E. Appleton, St. Mary's Hospital; Richard H. Williams, A. B. Kingsford, W. C. Carter, F. P. Kitson, W. J. Gilpin, and R. B. Hughes, University College; G. T. Giddings, C. Collier, J. T. C. Williams, and A. E. Kempthorne, London Hospital; J. E. Nihill, C. Lyddon, and C. H. Ashford, St. Bartholomew's Hospital; T. G. Scott and F. T. Frost, Guy's Hospital; E. E. Dalton, Charing-cross Hospital; E. M. Calendar, St. Mary's Hospital.

ROYAL UNIVERSITY OF IRELAND.—The following degrees and diplomas were conferred last week:—

DOCTOR IN MEDICINE.—Henry Anderson, Robert Bell, J. C. S. Burkitt, Howard Carr, Jacob Fairbrother, John S. Fogerty, John D. Kenny, Michael O'Brien, Leonard Redmond, R. H. Sproule.

BACHELOR IN MEDICINE.—Patrick A. Daly.

MASTER IN SURGERY.—Robert Bell, J. J. Brownlee, J. C. S. Burkitt, Howard Carr, John S. Fogerty, James C. Hood, E. J. W. Johnston, Alexander Lindsay, Robert McElwaine, Archibald P. B. Moore, Michael O'Brien, Richard M. Ralph, Leonard Redmond, R. H. Sproule, James Torrens, Samuel Wallace.

DIPLOMA IN OBSTETRICS.—James C. Hood, James F. Hunter, Alexander Lindsay, Samuel Wallace, Patrick B. White.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 3rd:—

Dundas, Mordaunt George, St. Thomas's-street.
Larkin Frederick Charles, Radcliffe-street, Everton, Liverpool.
Maggs, W. Adolphus, Hanover-square.
Peake, Solomon, Coventry.
Rashib, Edmund, Park-road, Wandsworth.
Williams, Edward Lloyd, James-street, Buckingham-gate.
Williams, Robert Richard, Llanberis, North Wales.

The following gentleman also on the same day passed the Primary Professional Examination:—

Burd, George Frederick, St. Bartholomew's Hospital.

MEDICAL MAGISTRATES.—Dr. W. T. Colby and Mr. Joshua Hartley, M.R.C.S., both of Malton, have been placed on the Commission of the Peace for the North Riding of Yorkshire.

MR. WALTER A. EMSLIE, M.B., C.M., has been chosen by the Free Church Assembly of Scotland as their medical missionary at Livingstonia, and he will shortly take his departure to that station.

ON the 5th inst., the foundation stone was laid of a coffee tavern, reading room, and workmen's dwellings which are being erected in connexion with the works and at the sole cost of Messrs. Chubb and Son in Old Kent-road. When the building is completed and fitted, it will be handed over to a committee of workmen, in order that the latter may themselves manage the whole affair.

THE sanitary authorities of Wolverhampton and South Staffordshire have decided not to accept the scheme of the local Drainage Commission for the drainage of the entire district for £250,000.

DR. MANSON (Banff) and Dr. Davidson (Wartle) were last week, in celebration of their jubilee as medical practitioners, invited to a banquet by the members of the medical profession in Aberdeenshire and neighbouring counties.

AT the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 8th inst., Sir W. N. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £70 was distributed among the several applicants.

THE last sessional meeting of the Western Microscopical Club was held on Monday, the 7th inst., at the residence of Dr. Danford Thomas, the coroner for Central Middlesex. A large and fashionable gathering assembled at a garden party given on the occasion. The band of the 18th Middlesex Regiment was in attendance. The whole affair was a great success.

THE STATE OF THE THAMES.—The attention of the Metropolitan Board of Works, the Thames Conservancy, the City of London Port Authorities, and the Royal Commission of Thames Drainage has been drawn to the present foul state of the river, and it has been proposed as a temporary expedient to deodorise the sewage at the two great outfalls in Barking Reach.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.—At the next annual meeting, to be held in St. Louis on Oct. 14th, 15th, 16th, and 17th, the following topics will be presented for consideration:—1. The Hygiene of the Habitations of the Poor. 2. The Hygiene of Occupations. 3. School Hygiene. 4. The Adulteration of Food. 5. Water Pollution. 6. The Disposal of Sewage by Irrigation and by Chemical Action. 7. The observable Effect upon Public Health of Official Sanitary Supervision. 8. The Work of Municipal and State Boards of Health.

NEW DWELLINGS FOR THE WORKING CLASSES.—On the 8th inst. the Prince and Princess of Wales opened in the crowded neighbourhood of Newport Market, Cranbourn-street, near Upper St. Martin's-lane, in the eastern part of St. Anne's, Soho, a new pile of buildings erected for the accommodation of the industrial classes. The block will lodge 257 families, or about 1250 persons. At the close of the opening ceremony a presentation of silver plate and other articles was made to Sir Sydney Waterlow and his co-directors of the company by which the building has been undertaken.

FORFARSHIRE MEDICAL ASSOCIATION.—The twenty-sixth annual meeting of this Association was held on the 3rd inst., when the following were elected office bearers for the ensuing year:—President, Dr. Keith Anderson, Arbroath; Vice-Presidents, Dr. Dewar, Arbroath, and Dr. Miller, Dundee; Secretary, Dr. Sinclair, Dundee; Treasurer, Dr. Macleod, Dundee. Council: Dr. Watson-Wemyss, Broughty Ferry; and Drs. Duncan, MacEwan, Bain, Johnston, and Templeman, Dundee. Local Secretaries were appointed as follows:—Dr. Dewar, Arbroath; Dr. Lawrence, Montrose; Dr. Mackie, jun., Brechin; Dr. Alexander, Forfar. Several papers were read, and it was decided to present to the House of Commons a petition in favour of Sir Lyon Playfair's amendment to Clause 10 of the Medical Act Amendment Bill.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting held at 3, New-inn, on the 9th inst., Dr. Robert Collum was elected Chairman, and Mr. Joseph Smith, of Rickmansworth, Vice-Chairman of the Committee of this Association. Great satisfaction was expressed at the progress which is being made in obtaining signatures to the petition both in London and the provinces, and at the hearty manner in which the local secretaries are aiding the object. A letter was read from Dr. Bruce Clarke, Hon. Secretary to the Association of Fellows, saying that the Fellows' Association is preparing a general scheme of reform, and asking to be informed of the views of the members. It was decided to hold a meeting at Belfast during the visit of the British Medical Association to that place.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ATKINSON, CHARLES S. ABBOTT, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the East Ashford Union.

CREAGH, WILLIAM, M.R.C.S., has been appointed Medical Officer for the Clifton District of the Tamworth Union.

DAVIS, ARTHUR N., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Assistant Medical Officer to the Second County Asylum, Forston, Dorsetshire, vice Henry George Peacock, resigned.

FAULKNER, HERBERT, L.R.C.P.Ed., has been appointed Medical Officer for the Seventh District of the Depwade Union.

GLYNN, T. R., M.D.Lond., F.R.C.P., Physician to the Royal Infirmary, Liverpool, has been elected to the Professorship of Medicine in the Medical Faculty of University College, Liverpool.

HULL, E. GORDON, M.D., B.S.Dub., has been appointed Medical Officer for the Withern District of the Louth Union.

JOLLY, SAMUEL AIRD, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Puddletown District of the Dorchester Union.

JONES, J. T., L.R.C.P.Ed., has been appointed House-Surgeon to the Flintshire Dispensary, vice Witham, resigned.

LYNAM, R. G., M.R.C.S., L.S.A.Lond., has been appointed House-Physician to the North Staffordshire Infirmary.

MURPHY, JAMES, B.A., M.D.Dub., &c., has been appointed Honorary Surgeon to the Sunderland General Infirmary, vice Dr. Ayr Smith, resigned.

PAIRMAN, THOMAS WYLD, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer and Public Vaccinator for the Fifth District of the Williton Union.

ROBINSON, CHARLES H., M.C.P., F.R.C.S.I., has been appointed Medical Examiner to the Equitable Life Assurance Society, for Dublin and District.

SAVILL, THOMAS D., M.D., M.R.C.P.Lond., has been elected an Assistant-Physician to the West London Hospital, vice Theodore Dyke Acland, M.A.Oxon., M.R.C.P.Lond., resigned.

SCANLAN, A. DE COURCY, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Westminster Hospital.

STONES, THOMAS, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Misterton District of the Gainsborough Union.

STOTT, HUGH, M.R.C.S., L.M., L.S.A.Lond., has been appointed Medical Officer of Health to the Friern Barnet Local Board.

WELSH, R. C., M.B., C.M.Ed., has been elected Assistant House-Surgeon to the Liverpool Dispensaries, vice Hadden, M.D., M.Ch., &c., resigned.

Births, Marriages, and Deaths.

BIRTHS.

HOWARD.—On the 6th inst., at Littleport, Isle of Ely, the wife of Wilfred Howard, L.R.C.P.Ed., M.R.C.S.Eng., of a son.

KIRKPATRICK.—On the 30th ult., at Clifton Villa, Alverstoke, Hants, the wife of Surgeon H. C. Kirkpatrick, M.D., Army Medical Staff, of a son.

POWELL.—On the 4th inst., at Seagrave-place, Cheltenham, the wife of W. Powell, M.R.C.S., of a son.

SHAW.—On the 1st inst., at Nicholas-street, Chester, the wife of Frank Herbert Shaw, M.R.C.S., of a daughter.

STEVENSON.—On the 7th inst., at Sandhurst Lodge, Gresham-road, S.W., the wife of Thomas Stevenson, M.D., F.R.C.P., of a daughter.

TICEHURST.—On the 3rd inst., at Silchester House, St. Leonards-on-Sea, the wife of A. B. Ticehurst, M.R.C.S. &c., of a son.

MARRIAGES.

CARNELLEY—HIGGINBOTTOM.—On the 8th inst., at St. Paul's Church, Withington, by the Rev. J. G. Denison, M.A., Matthew Carnelley, L.R.C.P., M.R.C.S., of Ruddington, Notts, third son of William Carnelly, of Fallowfield, to Jessie, younger daughter of the late Isaac Higginbottom, of Withington.

HARLAND—BAKER.—On the 3rd inst., at St. Pancras Parish Church, Henry Harland, M.D., of Tunbridge Wells, to Emmeline, second daughter of the late Henry Baker, F.R.I.B.A., of Gower-street.

THANE—KLINGBERG.—On the 5th inst., at the English Church, Heidelberg, George Dancer Thane, Professor of Anatomy in University College, London, to Jenny Anna Charlotta, eldest daughter of August Klingberg, of Stockholm, and cousin of Geheime Rath Professor A. von Bulmerincq, of Heidelberg.

WRIGHT—ANDREW.—On the 3rd inst., at the Parish Church, Fowey, Cornwall, Edward Wright, Surgeon, of Ollerton, youngest son of the late William Wright, Surgeon, of Pelham-street, Nottingham, to Catherine Bellman, youngest daughter of the late John Andrew, of Tregaminion, Cornwall.

DEATHS.

HEWARD.—On the 29th ult., at Bath, John Mitchell Heward, Surgeon, of Stamford, aged 54.

LA FARGUE.—On the 2nd inst., at Farncombe, G. F. H. La Fargue, M.D. St. And., aged 48.

WALKER.—On the 6th inst., at his residence, Ynysfaig House, near Dolgelly, and late St. James's-place, St. James's-street, London, George Alfred Walker, M.R.C.S. & L.S.A.Lond, aged 77.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

A PROSPECTUS of the arrangements in connexion with this institution for the sessions 1884-85 has been recently issued. As its name implies, the school is intended solely for legally qualified practitioners, no undergraduates being admitted, and no degrees being conferred. It is specially available for young graduates who wish to acquaint themselves with the practical duties of their profession, or for older practitioners who are desirous of taking up some special branch of medicine, or who wish to familiarise themselves with the modern advances in diagnosis and treatment. The instruction is given by means of clinics, subjects, and specimens. There are no lectures, except clinical lectures, and no demonstrations without subjects and specimens; the cases are not hurriedly seen and superficially examined, and each student has the most ample opportunities for making personal and deliberate examinations of individual cases. That the need of such an institution has been felt is evident from the fact that in the first session the number of medical men attending the courses was 100, a number increased in the second session to 118.

"BOILED LETTUCES."

To the Editor of THE LANCET.

SIR,—In the number of THE LANCET for June 28th, at page 1175, the statement is made that "spinach is necessarily excluded from the diet of the oxaluric patient." As a matter of some importance in the dieting of such patients, I shall be glad to know the facts on which this statement is founded.

I am, Sir, yours obediently,

July 7th, 1884. JOHN M. BALFOUR.

*** The word "necessarily" was an error in the sentence quoted. We meant to instance the *fact*, not to adopt or defend it. We should like to see this question discussed on the basis of *facts* in science. The Salsolaceæ (or Chenopodiaceæ) are characterised by the presence of a large quantity of alkali in their composition; this is combined with an organic acid. Spinach (Spinacia oleracea) and beet (Beta vulgaris) are prominent among the esculent plants of the order. A notable specimen of the family is Chenopodium quinoa, which is used as food in Peru, and called petty rice. It has the smallest starch grains known. Now, oxalic acid is obtained by the action of nitric acid on sugar or potato starch. Beet sugar will do as well as any other for this purpose, and as beet and spinach belong to the same order, spinach comes to be condemned. Moreover, spinach sometimes contains a good deal of lime, though not nearly as much as rhubarb, bistort, and many of the lichens. We confess it is not by any means plain to us why spinach should be singled out for a special anathema when beet-root and potato are not interdicted, and rhubarb is often, though obviously most improperly, allowed, or the blunder of taking it condoned. We fancy that if the objection to spinach specifically came to be scrutinised very closely, it would be found to have for its origin an impression that the "grit" so often found in imperfectly washed spinach is oxalate of lime, which, speaking generally, is not the fact.—ED. L.

A.B.C.—The operation was first deliberately and definitely advised by Paul Barbette in 1672. The first recorded operations are one by Theophilus Bonetus in 1769, and one by Velse in 1751.

"A TAILED CHILD."

To the Editor of THE LANCET.

SIR,—The case referred to in your issue of last week reminds me of one I published in your journal in 1866, a photograph of which was also attached. The tumour was succesfully removed by knife and écraseur.

I am, Sir, yours truly,

Donington, July 5th, 1884. E. W. JOLLYE.

Digitized by Google

Enquirens.—No; a doctor cannot legally claim a fee for giving evidence at an inquest held to investigate the cause of death of a person who died in the waiting-room of a hospital or dispensary. The fact of the inquest being conducted at another place than where the death occurred does not entitle the medical man to remuneration for his services.

"MIDWIFERRY."

To the Editor of THE LANCET.

SIR,—In the course of a working-class town practice, at one time very large, I had a similar experience to that of "Somnolens" in the country. I have long held a theory to account for it, which I am induced to mention. Without denying the influence of the excitement, &c., often attending the Saturday night, I believe the principal cause is the greater frequency of coitus on that evening than on any other of the week. When we consider that it is not only a time of unusual enjoyment, but the beginning of the most considerable period of rest throughout the week, the tendency to indulgence in this direction must be evident; indeed, I have no doubt of the fact. The effect of coitus in stimulating the uterus to contraction is very marked in many females towards the end of pregnancy. It is often immediately followed by contractions described as "movements," "risings," &c., during which the abdomen may be felt to become hard when the hand is placed over it. I have known such contractions produce rupture of the membranes, shortly followed by regular labour. With respect to the suggestion that the greater frequency of labour at this time is due to the greater amount of work performed by women on Saturday, it may be doubted if such is really a fact. Nay, the very opposite might be maintained. We all know how frequently "washing-day" seems to act as the exciting cause of parturition, and, for obvious reasons, this is seldom or never Saturday. I am, Sir, yours truly,

Partick, Glasgow, June 30th, 1884. ROBERT KIRK, M.D.

To the Editor of THE LANCET.

SIR,—Having carefully gone through a book of register of births for the past quarter in our district, it may interest "Somnolens" to learn that the births were as follows:—Saturday, 82; Sunday, 74; Monday, 62; Tuesday, 61; Wednesday, 77; Thursday, 65; Friday, 79; total, 500.

I am, Sir, yours truly,

July 1st, 1884. STATISTICS.

EPIDEMIC SPASMODIC COUGH (?) OF SEPTIC ORIGIN.

To the Editor of THE LANCET.

SIR,—Can any of your readers give me information as to the nature and most appropriate treatment of the coughs that have been prevalent during the last three or four months? In each case under my care there have been loss of voice first of all, followed by irritation of the throat about the upper part of the sternum, and a dry spasmodic cough, like whooping-cough, only without the whoop. Sometimes these are followed, after the lapse of two or three weeks, by thick copious expectoration, night sweats, and loss of appetite. The temperature keeps rising and falling irregularly, and seems to indicate some septic origin. In the first stages, alkalies and diaphoretics seem to do some good, but in the later, no treatment seems to be of much avail. The only thing that appears to be of service is Fletcher's syrup of the hydrobromate of iron and quinine. I have not seen anything exactly like the present epidemic before, and I shall be glad of some information on the subject. Other medical men I find are as much puzzled as I am.

I am, Sir, your obedient servant,

Surbiton, July 7th, 1884. F. P. ATKINSON.

Mr. Musgrave.—We know of no such commission.

Holtfield has not enclosed his card.

"SISTER GRACE."

To the Editor of THE LANCET.

SIR,—While thanking you for your generous remarks on "Sister Grace," I am afraid I cannot lay claim to the lofty motives you ascribe to me. I chose the subject of hospital life because, from a dramatic point of view, it was unused ground. A play having "the accident room" as the scene of two acts, and its chief characters drawn from hospital servants, has, at any rate, something novel about it. In seeking novelty I trust I have not been guilty of bad taste. Of course, the incidents occurring in "Sister Grace" are not of ordinary occurrence in our hospitals; but that such incidents may, and do, occur few will deny. In dealing with such a risky subject as hospital life I had to avoid any but the mildest realism, trusting instead to the comedy and pathetic element; and as love in some form is the central motive of all plays, it was essential to introduce a strong love element. I confess in representation this element seemed rather too obtrusive. "Sister Grace" was never intended to represent a complete orthodox picture of hospital life, and, full of faults as it doubtless is, it contains no ill-natured satire; and though the hospital characters were not intended to be perfect men and women, they were, I trust, human, and not unfitted for the positions they were supposed to hold. In short, and speaking as a medical man, I hope I am guiltless of all mud-throwing, either at my professional brethren or at institutions as dear to me as to them. From the reception accorded to "Sister Grace" on its production, and subsequently by the press, I feel I have no reason to be ashamed of my first dramatic child.

I am, Sir, yours truly,

July 9th, 1884. THE AUTHOR OF "SISTER GRACE."

"RUPTURE OF THE URINARY BLADDER."

To the Editor of THE LANCET.

SIR,—As your reviewer of my little volume on "Rupture of the Urinary Bladder" has attributed to the publishers, without reason, certain heinous offences which they have not committed, I must ask you to allow me to perform an act of justice, and bare the breasts of the real culprits for the reception of his deadly shafts. For any closeness of print and smallness of type of which your reviewer complains I am alone responsible, having been obliged to submit to the common-place necessity of proportioning my outlay on the work to the means at my disposal. It is painfully known to medical writers, if not to reviewers, that a distinctly literary work on a special and very limited subject is practically a "gift-horse" to the profession, and cannot be expected to return, directly or indirectly, to the author more than a fraction of the expenses. Hence their poverty, but not their wills, may compel them to present their sterile labours to the profession in a form less convenient to readers than otherwise they would have been glad to select. What your reviewer terms the "remarkable intercalation of a list of the author's published writings between the text and the index" was perpetrated by the printers, whose untutored minds were evidently unconscious of the existence of those thin partitions between propriety and impropriety to which the higher professional mind is so sensitively alive. Unfortunately, it is too late to rectify this momentous error in the present edition; but it may tend to mitigate its evil consequences if I point out that the so-called "advertisement" was inserted in this literary work as a literary notification for literary reference and literary purposes only, and that it is absolutely and, if need be, demonstrably free from any tinge of that commercial element which is generally considered to be the objectionable feature in the advertisement of professional works. I am, Sir, yours faithfully,

Finsbury-square, July 7th, 1884. WALTER RIVINGTON.

J. H.—We do not call to mind a book which treats the matter so generally as that mentioned.

MEDICAL EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—The question has often been raised whether examinations really test a man's knowledge and ability. Now, when the subject of overwork is occupying so much of the attention of the public, I should like to say a few words on this subject.

At the last Second M.B. Examination of the University of Cambridge a large number of candidates presented themselves. I have the pleasure of knowing two or three who went up from town after passing their "First College." They have all been unsuccessful in the anatomical and physiological part of the examination. On the other hand, men have got through who were just before rejected at the College of Surgeons. If examinations are any test, and not merely dependent on luck, this anomalous state of things ought to come to an end. It is only right that the standard of the M.B. Examination should be comparatively high. But certainly there is a limit to everything. In the physiology paper I see a question requiring the candidate to "describe the course of the nerves which are known to act upon the heart in the case of the dog or the rabbit." I suppose the so-called "accelerator nerves" are specially meant. Are Second M.B. candidates expected to possess a sound knowledge of comparative anatomy and physiology as well as human? If so, it is only fair that this should be stated in a schedule, so that candidates (especially those who go up from town) may, at all events, have an idea of what to expect. Looking over some of the London First M.B. (Honours) papers, I fail to find anything like the above question, though the London University gives its candidates a distinct schedule, and includes embryology. I am, Sir, yours faithfully,

July 8th, 1884. FAIRPLAY.

C. F. W.—Haviland's Chart, published, we think, by Stanford, Charing-cross.

UNUSUAL ACCIDENT WHILE BOWLING.

To the Editor of THE LANCET.

SIR,—The following being, I believe, a rare accident in one so young, seems worthy of record. The other evening I was called to see a young gentleman, aged sixteen, of slender build but athletic habits, who, while bowling overhand at cricket, suddenly felt a severe pain in the right groin. On examination, a direct inguinal hernia was found on the right, extending half way down into the scrotum. Pain being severe, a quarter of a grain of morphia was injected, and with some difficulty the bowel returned. Beyond temporary retention of urine, requiring the catheter once, he had no symptoms afterwards. There had been no previous hernia, but both external rings were larger than normal. Believe me, Sir, yours truly,

Leeds, June 27th, 1884. T. J. HUDSON, M.D., L.R.C.P.Lond.

REMUNERATION OF MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—I enclose the following cutting from a medical journal. How, I ask, can qualified men be so indifferent to their social status as to underrate the value of their services by undertaking such duties at so ridiculous a remuneration?—I am, Sir, yours obediently,

Halstead, July 7th, 1884. A UNIVERSITY MAN.

"Wanted, qualified in door Assistant. University man preferred. To assist in small practice and also in a chemical laboratory. Must know something of practical chemistry. Salary about £30, according to suitability. Plenty of time for reading.—Address, ——— ———."

Digitized by Google

Sanitas.—There is no hard-and-fast rule in the matter; but the Local Government Board have generally objected to a district medical officer undertaking another official appointment which takes him away from the localities where he has his Poor-law duties to fulfil.

PARACENTESIS FOR PLEURITIC EFFUSION.

To the Editor of THE LANCET.

SIR,—The following incomplete history of a case may prove of interest to some of your readers, should you consider it worth publishing.

Last July I was called to see a patient, and found him with his left thorax completely full of fluid. Unfortunately, I was very busy, and took no notes of the case at the time. However, at two operations I withdrew with the aspirator the whole of the fluid; the lung expanded very fairly, and the man made a good recovery, up to a certain point, when he insisted, contrary to my advice, upon going to work. I saw nothing more of him till the beginning of last month, when he came to my surgery, having been at work up to that day. He complained of nothing except that he had a lump on his back, which came suddenly about a week before. On stripping him, I found a swelling as big as a child's head, extending from the mid axillary line on the left side below the left scapula to the middle line of the back. Stethoscopically there was nothing to be made out, except a few friction sounds towards the base of the lung, which seemed to have quite recovered its normal state of expansion. His temperature was 99·2°. I had not the means to dress the swelling purely antiseptically, and so punctured it under a curtain of lint soaked in carbolic oil. I withdrew about a pint and a half of flaky serous fluid, and again applied carbolised lint. All went well until the fourth day, when I found my patient very feverish—temperature 103·6°—with an anxious expression of countenance, and he informed me he had had several rigors. On removing the dressing I found the wound discharging almost pure pus. I ordered a purge and a mixture containing five grains of quinine every four hours. He had no more rigors, and has been gradually improving ever since. The wound, however, has not yet closed, although it appears to be doing so, as I cannot pass the probe nearly so far amongst the tissues as I could a fortnight ago. I have no doubt that had the man remained quietly at home after the first operation until he had permission to work, he would have made a satisfactory and complete recovery.

The point that strikes one as peculiar is that such a collection of fluid could have gone on forming, and have finally forced its way out of the pleural cavity, without giving rise to more urgent symptoms. The man assured me that he had been at work the whole seven months that I had lost sight of him, and that he had been quite well, except a slight shortness of breath and a sudden pain in his side shortly before he noticed the swelling.

I am, Sir, yours truly,

Long Sutton, June 9th, 1884. J. EDWARD SMITH, M.R.C.S., &c.

POLLUTION OF THE THAMES.

To the Editor of THE LANCET.

SIR,—A party of us left London-bridge Pier by the morning Southend steamer, in order to have a day's rest in fresh open air. We had not reached Barking Creek before all on board were sickened by a "deadly insidious odour" arising in the form of sewer-gas, which continued without intermission for miles, polluting the air as well as the water of our deservedly so-called "noble river." This, I am informed, has been so for years past, and is gradually getting worse, and simply caused by the horrible system of discharging London sewage into the river at low, instead of high water, and so keeping it in the river, instead of its being carried right away to sea. This, in our century! whilst all England is full of a great Health Exhibition. Is our national spirit dead to allow our countrymen and women to be thus literally poisoned without a voice being raised in protest?

Sir, your are the representative of a great health journal, and I sincerely trust that by your giving this matter publicity something may be speedily done to remedy the evil.—Yours obediently,

July 9th, 1884. ONE OF THE PEOPLE.

M. R. M. (Bombay).—We have no practical knowledge of the effect of the agent, but think it very unlikely to be of any value as a preventive of contagion.

"SHOULD ENTERIC FEVER CASES BE ISOLATED?"

To the Editor of THE LANCET.

SIR,—All facts bearing on the above question are of great interest, so I venture to send the following.

Mr. and Mrs. R—— returned from Venice towards the end of March in this year to their home, a large and isolated house in the country. During their absence the house had been inhabited by six children with their governess, a sister-in-law of Mr. R——'s, and ten servants. On April 1st Mr. R—— was first seen, and presented well-marked symptoms of commencing enteric fever, certainly contracted in Venice. The diagnosis was afterwards fully confirmed, and the patient passed through a severe and typical attack of typhoid. Mr. R—— was nursed by three persons—his sister-in-law, mentioned as having been in the house during his absence, a trained nurse, and a sister who returned from abroad for that purpose. Of these three the two latter contracted typhoid, the nurse commencing on April 29th and the sister on May 5th. Every possible precaution had been taken with regard to disinfecting the excreta, &c. The rest of the household remained in good health.

I am, Sir, yours truly,

Burton-on-Trent, July 9th, 1884. HENRY E. BRIDGMAN.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

AT the Anatomical and Physiological examinations for the diploma of Member, on June 27th, the following were the questions in Anatomy submitted, of which the candidates were required to answer four (and not more than four) from 1 to 3 P.M.:—

1. Describe the elbow-joint.
2. Describe the dissection necessary to expose the extensor brevis digitorum from its origin to its insertion.
3. Give the attachments and nerve-supply of the two pterygoid muscles. What structures are in relation with the external pterygoid?
4. Describe the dissection required to expose the middle third of the back of the forearm as far as the bones and interosseous membrane.
5. Describe the cæcum, giving its investments, relations, and blood-supply.
6. Give the course and relations of the first part of the right subclavian artery. Enumerate the arteries with which its branches anastomose.

The following were the questions in Physiology:—

1. Describe one complete cycle of the heart's action. Give the relations of the sounds and impulse to the several events you name.
2. Give an account of the structure of a small bronchial tube. Assign to each of the textures its function, and explain its exact mode of action.
3. Describe the structure of the mammary gland. State the facts which tend to prove that milk is a secretion, and not the result of filtration.
4. Explain the mechanism of reflex and of voluntary micturition.
5. Describe the structure of a lymphatic gland. What is known of its function? Give the facts on which your statements rest.
6. What are the physical and chemical changes that accompany the contraction of striated muscle?

"BURIED ALIVE."

To the Editor of THE LANCET.

SIR,—I venture to trouble you with a few further remarks on this subject, as I wish to correct mistakes as to matters of fact in Dr. D. J. Williams's letter in the last issue of THE LANCET. I leave matters of opinion to others.

Firstly: "He describes the condition of the remains as if he had seen them." The fact is I did see them. Secondly: "The anomaly was seen by the sexton only." This is not true, independently of me. For, on seeing the strange condition of the remains, the sexton at once went to my servant-man, who immediately went and saw them. He then came and told me. I went and asked a medical man to go with me to see them, which he did. My servant saw them exactly as they were when the grave was opened. When the surgeon and I saw them the protruding limbs had been replaced in the coffin. Thirdly; I think I had "inquired" pretty "carefully" before I wrote to THE LANCET. I did not say that the coffin had not been screwed down, but that it was "possible" it might not have been. This, however, I corrected in my second letter to THE LANCET of June 7th, which Dr. Williams appears not to have seen. Fourthly: I did not express the opinion that the deceased had been buried alive, but wished to invite scientific men to explain the facts, and to tell us whether it was possible it might have been so. Fifthly: Dr. Williams is misinformed as to the quantity of water in the cemetery. I have taken funerals for seventeen years in all kinds of weather and have never seen any water in a grave. The son of a former sexton tells me he has seen a little water occasionally.

My second letter to THE LANCET mentions the fact which Dr. Williams mentions as if it were new, that the woman died on a Monday and was buried on the Friday following. I am glad to have elicited a number of letters to THE LANCET which prove beyond reasonable doubt that in this case the deceased was really dead when she was buried. Some of them, however, prove that cases of being buried alive have sometimes occurred. I may mention that I observed in the cemetery at Munich some years ago several dead bodies lying in coffins in a dead-house with a glass enclosure, exposed to public view, and was informed that the law required that no one should be buried till the body had first lain for three days in the dead-house. This, doubtless, was a precaution against burying alive.

I am, Sir, yours truly,

Vicarage, Llanelly, July 8th, 1884. DAVID WILLIAMS.

Mr. T. Strugnell.—1. It is for the coroner to decide whether a post-mortem examination is necessary.—2. Yes, it is competent for a jury to return a verdict of "Death from natural causes" when the medical evidence is that death may have resulted from poison. It is quite within their discretion, but we doubt the wisdom of such a finding.—3. We know of no special work, but the line of practice is well defined. Report the facts of the case to the coroner.

W. H. B.—We think our correspondent acted quite rightly, and, making due allowance for the "uncertainty of the law," that he could recover.

SUNSTROKE IN CHILDREN.

SIR,—I have this morning been called to a case of sunstroke in a young child. I send this notice as a caution to all who have charge of children.

I am, Sir, yours truly,

Pembridge-square, July 3rd, 1884. H. BOOTHBY DOW, M.D.

A DAY'S HOLIDAY.

WE are asked to state that in order to give 300 children and 100 poor women, members of mothers' meetings, an escape for one day from the heat and noise of South London into the fresh air and quiet of the country, donations may be sent to the Rev. J. W. Pitchford, St. Jude's Vicarage, Southwark, S.E.

Mr. Ernest W. Haydon.—We are not aware that the point has been raised.

Mr. A. Thomson Drake.—We are unable to extend our free list.

CORRIGENDA.—In the description of Dr. Blaikie Smith's Ether Inhaler, as published on July 5th, for "economical of the anæsthesia," read economical of the anæsthetic; and in the explanation of the woodcut, for "A, Respiratory valves," read A, Inspiratory valves.—In the Paris letter of June 28th, page 1184, in the tenth line from the bottom, for the word "frame" read *flame;* and in the succeeding paragraph, for Dr. "Harriot" read Dr. *Hanriot.*

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Henry Thompson, London; Dr. Colcott Fox, London; Mr. Boothby Dow, London; Dr. Cameron, Huddersfield; Dr. Wakefield, Aix-les-Bains; Mr. Balfour, Brighton; Mr. J. Campbell, London; Mr. Jollye, Donington; Mr. Haydon; Dr. Harkin, Belfast; Mr. Van Praagh, London; Mr. J. A. Philip; Mr. Powell, Beckenham; Mr. Pohl, Liverpool; Mr. D. Dinin, Paris; Dr. Ranking, Mean Meer; Dr. J. Seaton, Ospedaletti; Dr. H. N. Carter, Bombay; Mr. P. H. Kidd, West Hartlepool; Mr. J. M. Balfour; Messrs. Sleeman and Co., London; Mrs. Fedarb, London; Mr. Day, Aden; Mr. Browne, London; Mr. McDonald, Manchester; Dr. Le Grande, Queen's-town; Mr. Davies, Tenbury; Dr. Wyer; Mr. Bura, Shrewsbury; Mr. Blora, Leeds; Mr. Collies; Dr. Hart, Corby; Mr. West, Bickley; Mr. Grant, Birmingham; Mr. Armstrong, Manchester; Messrs. Kegan Paul and Co., London; Messrs. Burgoyne and Co., London; Mr. Douglas, Sunderland; Mr. Worton, Pontypool; Mr. Smithson; Dr. Hale White, London; Dr. Althaus, London; Mr. Butlin, London; Mr. T. E Gibb, London; Dr. Blaikie Smith, Aberdeen; Mr. Lawson Tait, Birmingham; Mr. Pulbrook, London; Dr. Robertson, Kimberley; Mr. J. St. T. Clarke, Leicester; Rev. D. Williams, Llanelly; Dr. Lunn, London; Mr. F. Guthrie; Mr. Bridgman; Rev. J. W. Pitchford, London; Dr. Dickenson; Mr. Forbes, Blairerno; One of the People; M.B., C.M.; Physician; M.R.C.S.E., L.M., L.S.A.; Public Vaccinator, Cardiff; Medicus.; Z., Birmingham; R. A. A.; Epsilon; M.D., Belper; J. H., London; J. D. B.; Sanitas.

LETTERS, *each with enclosure,* are also acknowledged from—Mr. Crasweller, Clapton; Mr. Phillips, Hanley; Dr. Sutherland, Castletown; Mr. Davidson, Appleby Magna; Mr. Rawling, Colchester; Mr. Jones, Carnarvon; Mr. Hankin, Dublin; Mr. Roberts, Croydon; Dr. Ashdown, Tetbury; Mr. Taylor, Retford; Dr. Mair, Bayswater; Dr. Scatliff, Brighton; Dr. Tashby, Guernsey; Dr. Waller, Peterborough; Mr. Bridgman, Glaidbarn; Mr. Fenwick, Dansford; Mr. Long, Blackburn; Mr. Greenwood; Dr. B. Smith, Aberdeen; Mr. Rollin, Jersey; Mr. Tattersall, Victoria; Mr. Orde; Dr. Jennings; Mr. Matheson, Milford Haven; Mr. Carnelly, Manchester; Mr. Dukes, Rugby; Mr. Corbishly, Macclesfield; Mr. Gutteridge; Mr. Menzies, Edinburgh; Miss de Lattichau, Holloway; Mr. Lloyd, Yarmouth; Lady Superintendent; M. Medical Diary for the ensuing Week.

Monday, July 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

Tuesday, July 15.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, July 16.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, July 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, July 18.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

Saturday, July 19.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Lectures

ON SOME

IMPORTANT POINTS IN CONNEXION WITH THE

SURGERY OF THE URINARY ORGANS.

Delivered at the Royal College of Surgeons,

BY SIR HENRY THOMPSON, F.R.C.S.,

SURGEON EXTRAORDINARY TO HIS MAJESTY THE KING OF THE BELGIANS, PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ENDRIBIS PROFESSOR OF CLINICAL SURGERY, ETC.

LECTURE VI.

The Results attained by Lithotomy and Lithotrity in Great Britain during the present Century; with an Analysis of more than 800 Cases by the Author, presented therewith.

[THE lecturer commenced by observing that before entering upon the question of results of treatment there were two considerations to be dealt with, demanded by the great fact of modern practice—namely, that lithotrity is almost universally applicable to the cases of adult calculous patients. He continued]:—

The first consideration is that it is essential to determine, and if possible to define, what is to be understood henceforward by the term "a stone in the bladder." The second is that, in estimating the value of treatment for calculous cases, the result of a single operation for stone can no longer be regarded, as it invariably was until a few years ago, as a fact of the highest importance, and as synonymous, or almost so, with the history of a calculous case; since such an operation may now be only a single incident, and not always a very considerable one, which may be repeated sometimes on several occasions, in the course of such a history. The importance of these statements will appear as we proceed. We will first consider what is in future to be regarded as a definition of the term "stone in the bladder."

When a calculus was removable only by lithotomy—a period, moreover, which was anterior to the discovery of anæsthesia—the magnitude of the operation almost invariably prevented the surgeon from proposing it, or the patient from accepting it, until painful symptoms had been endured for a considerable period of time, and the stone was at any rate no longer small. Indeed, among the operators of the eighteenth century it was considered not always desirable to attack a stone when first discovered; but rather that, if small, it should, to use a term then in vogue, be allowed to "ripen," in other words, to increase in size somewhat before the operation was performed. Again, it was very rare to operate on the same individual twice. A man who had once passed through the ordeal of a cutting operation was, if he had the misfortune to form another stone, not lightly advised by a cautious surgeon to undergo a repetition of the process, and was himself naturally reluctant to submit to it. Now and then an individual was operated on twice; but it was a rare occurrence. One or two histories are on record of fortunate patients who survived a third operation; but such an event was one of the extremest rarity. The result of these conditions was that a great number of calculous patients died of their malady, relieved, it is true, for a time by medicines, but not subjected to any operation. I am quite sure I am within the limits of truth if I say that, regarding the class of elderly calculous patients, probably not more than one in fifty during the last century was submitted to operation. The stone, although present, was often not suspected to be so, much less was it sought for; and its symptoms were mostly attributed to "strangury," a term which formerly covered several forms of urinary disease, not then distinguished. If a search were made, it was often fruitless, because the instruments were faulty, and the experience, as well as the tact which comes from it, were small. In the country districts there were very few men who could or would undertake the operation; and the conditions of locomotion at the period referred to rendered a journey well-nigh impossible for most of the suffering patients. Hence it was that the itinerant lithotomist supplied a pressing want in times gone by. Then the dread of the operation itself and of its dangers deterred a majority of those sufferers who were within reach of aid from invoking it. The result of these various circumstances was that a very large proportion of calculous patients were children, who, unable themselves to exercise any will in the matter, and being known by their relatives to incur comparatively less risk than their seniors, were without difficulty placed under the care of the operator.

You will see, then, that in all the past experience of calculous disease, anterior to and terminating with the year 1836 or thereabout, an operation for the stone was necessarily a very important fact; and was almost invariably the culminating point of the long history of suffering in the individual affected. The event was looked forward to as demanding great courage on the part of an adult patient to confront not only the torture of the operation but the chance of a fatal result. Hence a list of the several stone operations which a surgeon had performed was equally a list of all his stone patients and of their entire histories; and the number corresponded with the number of his cures and of his failures. And when we come to analyse the work of the old masters you will see how the remarks which have been made respecting the vast importance to an adult patient of an operation are warranted from the fact that almost all their cases were those of children. And this, too, explains the large proportion of recoveries which some of their lithotomy records present. Indeed, compared with our experience of to-day, an operation for stone was rare indeed among elderly men—not that stone was less frequent then, but that, on grounds already referred to, it did not come to the operating table. Now, in order not to expend time unnecessarily, I shall adduce but one illustration of this fact, taking it from the figures of our great English master, Cheselden. The well-known record which he published at the end of his career amounted to 213 cases of operation, of which 135 were under ten years of age, with three deaths; only 14 were above fifty years of age, and of these 6 died. By way of marking the contrast which the records of to-day furnish, the cabinet of my own calculi there contains the cases of 595 male patients of that age alone, out of a total of 812, or more than forty times his number.

But the great fact of to-day which marks the difference between this age and the past is that we are able now to remove a stone even of considerable size from the bladder of the elderly adult with a risk to life which, in most instances, is very small, and which is serious only in cases of exceptional character. The consequence is that a moderate-sized calculus is generally disposed of as soon as it is discovered, because uncontrollable dread of a dangerous operation is no longer an occasion for delay. At the same time it is equally the aim of the surgeon and the interest of the patient that a calculus should be discovered as early as possible in order that it should be removed when small. It follows further, and this is a matter of the highest importance, that if the calculus recurs the operation is easily repeated, whether it be a new product of uric acid or of oxalate of lime which has recently descended from the kidneys, or a renewed accumulation deposited from decomposing urine in an incompetent bladder which has long been emptied by the catheter. In either case lithotrity is available time after time, if need be, to afford relief; and a patient's life, which formerly depended on the result of a single formidable cutting operation, is now indefinitely prolonged, for many years on easy terms by an occasional recurrence to the lithotrite. I repeat, therefore, the statement that the record of a single calculous operation and the history of a calculous patient are now very far from being synonymous terms.

Hence I desire to place on record the following deduction as most important in the interest of accuracy in reporting and in observing results—viz., that a computation of the results of lithotrity is not possible by the numerical record of cases only, and by the bare exhibition of a list of so-called "cures" and deaths; but that the entire record of the calculous patient's history—its commencement, the number of operations, the quantities of debris removed, and the incidents of the subsequent history, so far as they can be obtained—is essential in order to furnish evidence in regard of the treatment employed, and to render the case useful as a contribution to surgical experience. And it follows also that, in speaking of "a stone"—which no longer necessarily means a considerable product of accretion during years, such as that for which a patient was formerly cut,—a certain understanding

Digitized by Google

ought to exist among surgeons in order to indicate some limit to the meaning of the word. At any rate, it is now necessary in all cases that the composition and weight should be recorded, while it might be convenient to apply the terms "stone" or "calculus" only to such aggregations of material as attain a certain amount of size or weight. I think, however, it will be generally agreed that when a bladder is found for the first time to contain a calculus, whether urate, oxalate, or phosphate, which is too large to be expelled by the natural efforts, the crushing and removal of it (together with others, if such be present), so as to empty the bladder, necessarily constitute an "operation for the stone," whether it (or they) be large or small. If a small stone only is present the patient is fortunate in having it detected, because it would inevitably have become larger had it not been discovered, and the operation is then attended with a corresponding increase of risk. Some patients will produce with great frequency a small acid calculus so that every three months or so during several years a small pisiform body, usually uric acid, drops into the bladder, and if too large to be expelled remains there. Such a patient may most advantageously avail himself of lithotrity every two or three years during a considerable portion of adult life. Nevertheless be it remarked that in five cases out of six he may, by well-chosen diet, speedily overcome the tendency to produce superfluous uric acid, and cease to form these calculi. But there is another type of patient who rapidly forms calculus, more rapidly even than the preceding. I refer to the patient who passes all his urine by catheter and is the subject of phosphatic urine. In a certain proportion, happily small, of these cases a healthy acid condition of the urine is not attainable, and small phosphatic calculi are formed with surprising rapidity. I have had several patients under my care whose bladders require clearing by means of the lithotrite and aspirator as often as once or twice a year. On the very first occasion, perhaps, a phosphatic calculus of considerable size has been removed, and again, in two or three years another, and these are fair examples of "stone," regarding the sense in which it has been customary formerly to employ the word. But at length the chronic condition described above is reached; smaller calculi are rapidly produced, and now the result of each operation has no right to be so regarded, if we maintain in future the idea hitherto associated with the term "stone." Hence I have in practice termed these small and recurring bodies "concretions," in order to draw a needful distinction between these and the large primary formations. I have removed at least 200 or 300 of these small bodies without placing them in my list of stone cases. But there is no recognised rule to this effect, and it is confessedly not easy to construct one, and I have long felt how open the door is to error unless one is careful to avoid misrepresentation in regard to this matter. That such small concretions have been made to do duty in augmenting the figures which represent cases of stone I have good reason to know. By way of suggesting a limit I think that after the first phosphatic calculus has been removed from a patient, no subsequent phosphatic formation of the kind described weighing less than about a drachm should be permitted to rank as a second stone, but should be described as a concretion.

It is strictly in accordance with the plan thus advocated that I have treated from the very first all the cases of my own, which are now exhibited in the cabinet before you. It consists entirely of my own cases, and of all those cases without exception. Each number in the catalogue, from No. 1 onwards, denotes not a mere operation, but a separate individual, who has been operated on either by lithotomy or by lithotrity; so many numbers, so many individuals. To each number is added his name, age, and a record of the one or more operations he has submitted to, with the result; and as much of the subsequent history as, in a good many cases, I have been able to obtain. I shall merely add now that the number of individuals is 716, and that the total cases of operation, embracing both lithotomy and lithotrity, are 812 in number. For I have to submit for your consideration some very interesting matter in connexion with the chief statistical records which precede my own in date, for the purpose of estimating the results of operations for stone, not merely by lithotomy alone, but also during that transition period which intervened between what may be called the two epochs, respectively, of lithotomy and lithotrity; for it will appear, if we recall the brief retrospective sketch given at the last lecture, of stone-operating during the present century, that its history is naturally divided into three chief stages.

I. The era of lithotomy pure and simple, when the operation was applied to cases of every description.

II. The era in which lithotrity, having appeared, was adopted for a certain proportion of patients for whom the crushing was believed to be better than the cutting operation, which latter, on the other hand, was preferred on certain grounds for other patients; the relative numerical proportions submitted to the two procedures differing in the practice of different operators, but approximating more or less to equal moieties of patients to each method.

III. The era which appears now to be established, in which lithotrity may be regarded as applicable to all adult cases as the rule, the exceptions of any kind, besides the cases of children, being extremely few.

1. Now, as an example of the first period, or that of lithotomy pure and simple, I cannot adduce a more complete or trustworthy record than that which exists in the archives of the Norfolk and Norwich Hospital. During the first sixty years after the establishment of that hospital, where the best provincial experience in our country was to be found, 704 cases of all kinds and ages were operated on. The period referred to commenced about 1770, and ended about 1830.

Of the 704 cases, 35 were females, with two deaths; 343 were male cases under twenty years, with 27 deaths—a mortality of one in thirteen cases, or 8 per cent.; 326 were male adults, with sixty-four deaths—*a mortality of one in five cases, or 20 per cent.* Among these there were only 75 males over sixty years of age, among whom the deaths were 22; or one death in every 3½ cases, or 30 per cent.

2. We now consider the transition period, which may be roughly regarded as commencing about 1835, and ending between 1860 and 1870. The experience of two well-known operators will admirably illustrate the results attained during this epoch by the nearly equal division of adult male cases between lithotomy and lithotrity. I am happy in being able to present to you, first, the exact and complete experience of my old friend Dr. Keith of Aberdeen. He left it to me to utilise at such time and in such manner as I thought best. I have before casually referred to it in general terms, and I think I cannot now more worthily commemorate the work of that kind-hearted and excellent man, and most able surgeon, than to record it first fully here in our College. Keith operated chiefly between 1835 and 1868. He recorded all his facts with great care and attention to detail, his own manuscript notes being in my possession, and I have made the following analysis of them:—

Dr. Keith operated on a total of 304 cases at all ages. Of these four were females:—

Lithotomy	2	No death.
Lithotrity	2	

Twenty-three were children:

Lithotomy	19	One death.
Lithotrity	4	

27, leaving 277 adult males.

Of these 277 adult males, 161 were by lithotomy, with 38 deaths—1 case in 4¼, or 24 per cent. 116 were by lithotrity, with 7 deaths—1 case in 17, or 6 per cent. A total of 277 adult males, with 45 deaths—*1 case in 6½, or 15 per cent.*

It will be in the recollection of most of us, that in the year 1865, Sir William Fergusson occupying the chair which I have now the honour to hold, presented the sum total of his experience to the College. His cases were fewer in number than those of the list just given, and they included a larger number of children.

Sir William Fergusson operated on a total of 271 cases at all ages. Of these, 52 were children, all lithotomy, with 2 deaths—1 case in 26, or 4 per cent., leaving 219 adult cases. Of these 219 adult males (comprising a few female cases, number unknown), 110 were by lithotomy, with 33 deaths—1 case in 3⅓, or 30 per cent. 109 were by lithotrity, with 12 deaths—1 case in 9, or 11 per cent. A total of 219 adult males, with 45 deaths—*or 1 case in 5, or 20 per cent.*

3. We now enter on the third epoch, or that in which lithotrity is the manifest rule of practice for the adult, and lithotomy the occasionally necessary exception. And this may be illustrated by my own cabinet of calculi, now before you, which was commenced shortly before 1860. A small early portion of it may perhaps be regarded as almost belonging to the period just passed by; but as at the outset I aimed at accomplishing as much as possible by lithotrity, it belongs in reality to the present epoch.

Digitized by Google

In this country lithotrity was, before 1860, as we have already seen, slowly becoming responsible for a large share of the work in the hands of the leading operators. In most parts of the kingdom, however, it was still employed only for exceptional cases. But I was strongly of opinion that it was not sufficiently appreciated in this country, and that it ought to be much more widely employed, and I persistently urged this view in my earliest writings.[1] Accordingly, among my first 200 cases of adult males, only forty-eight, or not quite one-fourth, were submitted to lithotomy. The proportion of cutting operations then gradually diminished henceforward to about one case in seven or eight. But in the end of 1878 I commenced to employ lithotrity at a single sitting, doing so extensively at the commencement of 1879. Since that date I have performed 196 cases by this method solely—that is, during a term of five years and a half, and only fifteen lithotomies—in all 211 cases, the mean age of the entire number being upwards of sixty years. But, taking my last 125 operations up to the present date on adult calculous patients, only four have been treated by cutting; all the others—viz., 121—were cases of lithotrity at a single sitting.

The total result of all my operations by carefully adapting the two procedures during a period of about the last twenty-five years, is as follows:—I have performed 812 operations on cases of all ages. The number of individuals on whom these operations have been performed is 716; some of the lithotrity patients having, of course, been operated on more than once, as will be stated hereafter. Of these cases 13 are adult females—10 by lithotomy with one death, and 3 by lithotrity; 15 are children—12 by lithotomy, with one death, and 3 by lithotrity. Then two operations (one a suprapubic lithotomy) for foreign bodies recently introduced, There remain 782 cases of operation on the adult male.

Of these 782 adult male cases, 110, or one-seventh of the entire number, were by lithotomy, with 39 deaths—one case in almost 3, or 35 per cent.; 672 were by lithotrity, with 43 deaths—one case in 15½, or under 6½ per cent. A total of 782 adult male cases, with 82 deaths—*one case in 9½, or 10½ per cent.* It is worthy of remark that among the adult males no fewer than 595 individuals were upwards of fifty years of age at the date of operation. I may now add that of the 716 individuals, 61 were operated on a second time, at various intervals, when a second stone of considerable size was developed; evidence existing, in long-continued absence of symptoms after the first operation, that the calculus was undoubtedly a new formation. Nine patients were operated on a third time, three patients a fourth time, and two as many as five times. It is worthy of note that each of the last named, the history of whose operations extends over a period of from twelve to fifteen years, are now living in comfort. One has passed more uric acid than any man I have seen, unless the patient, No. 62 in the series, from whom I removed four large calculi at four different periods in the course of about sixteen years. In both cases, each succeeding calculus of large size was a fresh deposit of uric acid, which each still continued to excrete largely, and not the mere accumulation of phosphates often so abundantly produced in a bladder incapable of emptying itself.

In analysing the results of the preceding table it is unnecessary to say that it is not possible to make any comparison as to the relative value of lithotomy and lithotrity. The position of the two operations towards each other is no longer one to invite comparison, but is that of complementary relation. Each accomplishes a part for which the other is less competent; nor, for the same reason, is it any longer possible to compare the results obtained by different operators in regard of employing either method, unless each operator is guided by the same principle in applying them, for it is obvious that the surgeon who adopts lithotrity for [illegible] of his cases—that is, for all but those which are [illegible]—necessarily obtains for his lithotomy only an unfavourable residuum of exceptionally bad patients. And it is not to be forgotten, as Keith has remarked, that when an operator obtains reputation, he attracts the worst cases, and is compelled to deal with some of the most unfavourable of the disease, unless he refuses such applicants which I have never pursued. During my [illegible] I have refused operation to six patients in such instance because I thought the proceeding [illegible], hopeless, or impossible of performance. [illegible] I regretted my decision, for the patient lived long and suffered very severely. Hence the lithotomy of an operator who employs the knife only for the worst case in eight or ten cannot be compared with that of the surgeon who applies it to a large proportion of his cases, and therefore to a considerable number of healthy and promising patients with not very large stones, such as I have always treated by lithotrity.

It is the sum total of result obtained by employing the two procedures which is to be regarded as the measure of the surgeon's success. And I think I may say that a list of 782 cases in male adults, the mean of whose united ages exceeds sixty years, with 82 deaths, or one in 9½ cases, is a result which will be held to justify the selection and adaptation of the method to the case, which has been adopted throughout this series. I venture to say that it is a result which has not, certainly to my knowledge, hitherto been realised. Thus we saw that Cheselden, with patients of this age, lost 6 in 14, or one death in 2·3 cases; that the Norwich rate for male adults was one death in 5 cases; that Keith advanced to a rate of one death in 6½ of his adults, by both methods; that Fergusson, who had many bad cases sent him to King's College Hospital, lost one in 5 both methods. But while the sum total of my whole work has been one death in 9½, the result of the last five years, since I have adopted the one-sitting operation, has been still better—namely, one death in 12½ cases (211 elderly adults with 17 deaths), or 8 per cent. While, if I take my very last 125 cases up to this date, and already referred to as containing only 4 cases of lithotomy, I have to report 6 deaths only (of which 2 were from the cutting operation), making only 1 death in 20, or a rate of less than 5 per cent. And I further beg you to observe herewith, that the clinical notes made at the time in every case are presented to you here; each patient with his own proper name, together with the name of the attending medical man whom I met in consultation in each instance; and finally, the calculus of almost every patient is presented also. In every single case, therefore, in the whole collection, I am responsible for every fact stated, and offer with it absolute guarantees of its accuracy. No labour has been spared to pursue this system throughout, and my satisfaction is complete at being thus enabled to offer to the College, if they will do me the honour of accepting it, a faithful record of one man's practice during five-and-twenty years, as complete and as elaborately reported as it has been possible to make it.

[The lecturer then proceeded to show that calculus was far more frequent in elderly men than in children; that the symptoms in the former were often very slight and had been mostly overlooked, and that the great practical lesson from this fact was the necessity for discovering the calculus in its early stage, and for crushing it at once, when the risk of danger in doing so was practically almost nothing. He then discussed the conditions which should determine the choice of operation when the calculus was extremely large, and concluded that only for such should lithotomy be employed in the adult, as well as for most of the cases in children. He then continued:]

There is unquestionably a growing expression of dissatisfaction among surgeons, especially abroad, with the lateral operation for stones of unusually large size. I have for some time fully shared in that feeling. No incisions can be made in the region which belongs to that operation through which a calculus of three ounces or more can be extracted. Laceration, either avowedly made by instruments, or but half concealed under the name of gradual distension, invariably takes place, and that affecting very important structures, often to a large extent. Hence it is that the suprapubic operation has always invited consideration when the stone is exceptionally large; but the conditions sometimes met with, especially in corpulent subjects, have often presented peculiar difficulties and dangers, which indicated that if Scylla has been avoided above, Charybdis appears to be equally dangerous below. A modification of the operation, however, has recently taken place, if not originated, at least, first executed by Professor Petersen of Kiel, and described by him in 1880, which gives a new and improved position to the high operation. The improvement suggested consists in ensuring, to a degree not before attained, the raising of the bladder above the pubic symphysis, and the steadying it in that position during the operation. These objects are thus attained. The patient, lying on his back, and under the influence of an anæsthetic, the bladder is first distended with a weak solution of boracic acid, in quantity from ten to twelve ounces if possible,

[1] See THE LANCET, Jan. 21st, 1860.

Digitized by Google

which must depend on the condition of the organ. The penis is then firmly tied; nothing is better than an indiarubber tube for the purpose. Then a pear-shaped bag of indiarubber, tolerably stout, so as to retain that form, and capable of holding at least sixteen ounces of fluid, is folded longitudinally and introduced into the rectum. By the tube which forms its apex, and is supplied with a stopcock, water is forced in so as fully to distend the bag *in situ*. The outline of the bladder will now be traced above the pubic symphysis. The usual vertical incision is made, and dissection carried down to the bladder, with the usual precautions with which we are familiar. The ease and the certainty, however, which are ensured by the firm position of the bladder in this system, render it much superior to the old one. I have operated by the high operation twice only, and that before the introduction of the new method. Since that time I have met with no case which I have not been able to deal with satisfactorily by lithotrity at a single sitting, of which several examples are placed before you—the calculi weighing from one to nearly three ounces. The next case which offers for which the knife is required, I shall almost certainly submit to the high operation, with Petersen's modification. And the only reason why I have not yet performed it is that I have easily and successfully employed lithotrity in cases precisely similar to those for which the French surgeons are at present adopting Petersen's procedure.

Lecture

ON THE

PRINCIPLES WHICH UNDERLIE THE

CONSTRUCTION OF APPLIANCES FOR THE REMOVAL OF SICK AND WOUNDED.

By ROBERT LAWSON,

INSPECTOR-GENERAL OF HOSPITALS, LATE PRESIDENT OF THE EPIDEMIOLOGICAL SOCIETY, FELLOW OF THE STATISTICAL SOCIETY.

AT the request of the Committee of the Volunteer Medical Association I have undertaken to give a lecture on some subject within the range of those on which it is the object of their organisation to diffuse information; and it appears to me I cannot meet their wishes more advantageously, at the present time, than by pointing out the principles which underlie the construction of the appliances recommended for the removal of the wounded from the field of battle. Such appliances are of great use in moving sick and wounded elsewhere; but inasmuch as the transport of individuals who have sustained severe injuries in action is their most prominent and important employment, all their details require to be arranged with especial regard to the requirements of this service. Military operations in which this country is engaged are usually carried on at some point with which our communications are by sea; this requires that our transport vehicles should be constructed so as to permit of their being taken to pieces, and packed in the most compact form for stowage on board ship.

The first service to be rendered to a man disabled in action is to remove him to a position out of fire, where his injuries may be examined and the requisite treatment applied, to enable him to be sent on to the hospital where it is intended he should be retained for cure. To facilitate this a great variety of appliances have been recommended at various times, and employed more or less, as the materials for their construction were available. These are now pretty generally displaced by the field stretcher.

Field Stretcher.

A field stretcher is essentially a hand litter, with the assistance of which two bearers can remove a wounded man, with the least exertion on their own part, and with the least injury to the patient, and it will approach perfection in proportion as it realises these ends. The stretcher usually consists of two side poles, to which a canvas or net bottom is attached on which the patient is laid, and there are cross pieces of wood or metal to prevent the poles coming together when raised from the ground. Legs or feet are frequently added, to keep the bottom off the ground when a sick or wounded man is on it. These elements have been combined in a great variety of ways, according to the views of individual constructors, some of which have proved pretty successful, while others can be considered little better than failures.

To obtain a clear idea of what is required in a field stretcher, it is necessary to analyse the motions of the bearers while carrying it. While they are standing still, with their feet together, a perpendicular line passing through the centre of gravity of their bodies will touch the ground between their feet, but, as soon as they begin to move, they must bend their bodies to that side on which a foot touches the ground so as to bring their centre of gravity over the point of support, and thus maintain their equilibrium; the effect of this is to cause a motion swaying from side to side with each pace of the bearers, which might prove beneficial if not counteracted; by making the bearers walk out of step, however, the sway of one to the right is neutralised to a very large extent by the simultaneous sway of the other to the left, and the individual carried is but little affected.

There is another motion, which is in a vertical direction, which requires a different mode of treatment. Let there be two bearers, 5 ft. 8 in. in height, carrying a stretcher; when standing, with their feet together, the perpendicular from the centre of gravity of the body of each to the ground will pass through his hip-joints, and the distance of the centre of motion in these to the ground will be 34 in. If now one foot be advanced 30 in. (the usual military pace) and placed on the ground, while the other remains in its original position, the distance from each hip-joint to the point of support of each foot will remain 34 in., but the perpendicular from the joint to the ground will be 30½ in. only, or 3½ in. less than when the feet were together; so that the body of a man about the height mentioned, with anything he may be carrying, is raised and falls again 3½ inches every pace he takes, when these are 30 in. in length. With paces of 20 in. long the perpendicular from the hip-joint to the ground in the middle of the pace is 32½ in., so that the rise and fall is 1½ in. only, instead of 3½ in. with the longer step. Surgeon-General Longmore, in his Treatise on the Transport of Sick and Wounded Troops, at p. 171, gives some actual measurements, which coincide exactly with those arrived at above from calculation, when there was no one on the stretcher, but with a man carried they were with each length of step three-quarters of an inch more. He proceeds, "Of course, in marching at either pace there is an alternate rise and fall to the same extent, and the effect of this on the elastic poles of a stretcher can be readily imagined."

A stretcher with light side poles, such as circular poles of 1½ in. in diameter, even with the most careful walking will bend much more than the distances given above as due to the motions of the bearers; the effect on the person carried is a vertical oscillation greatest over the lower part of the chest, the abdomen, and thighs, less towards the head and feet, and repeated at every step. Serious cases of ordinary sickness would be much incommoded if subjected to such a trial, but for men with severe wounds in the trunk or fractured thighs it would be little short of torture. As regards the bearers, the descent of the stretcher from its highest point, with the body of the person upon it, is to be regarded as a body falling under the action of gravity, and every inch it proceeds beyond that due to their movements in walking generates an additional force acting downwards, which might be avoided, but which they have to meet by additional exertion of the arms, shoulders, and trunk. To give a quantitative illustration of this, let it be assumed that a stretcher with a wounded man upon it weighs 150 lb., and that the vertical oscillation due to the motion of the bearers amounts to 4 in., but, that owing to the yielding of the side poles the mean fall of the body is 2 in. more; the additional force generated is equal to that required to raise 150 lb. 2 in. in the same period of time, or its equivalent to raise 10 lb. 30 in., or 2½ ft. This is the force produced by the fall, but inasmuch as the body has to be raised 2 in. again, the actual force thrown on the bearers is that required to raise 150 lb. 4 in., or 10 lb. 5 ft. If, now, by adding 10 lb. more material to the side poles, they were sufficiently stiffened not to yield the additional 2 in. above mentioned, the extra work thrown on the bearers would be to raise this weight 4 in. only, which is rather less than one-fifteenth of the extra work thrown on them by the yielding of the weaker poles.

There was a considerable display of ambulance and field hospital equipment at the Paris Exhibition in 1867, and in 1868 a committee (of which I was a member) was appointed in this country to examine into the condition of the British equipment, and to suggest improvements. The field stretcher then in use had round side poles of ash, 8 ft. long and 1¼ in. in diameter; it weighed 16 lb. The objections to it were the great amount of vertical oscillation inseparable from its use, and the want of any means of keeping it off the ground while the bearers were resting, or assisting the wounded man in their charge.

A stretcher which had been adopted by the French army authorities shortly before was placed in the hands of the Committee. This had side poles of ash, square in transverse section, with an area very close on 3 square inches, and of the same thickness throughout, except where reduced at the ends for the bearers to grasp. It weighed 20 lb., and in the extensive trials of it at Aldershot, under my own observation, it was found remarkably free from vertical oscillation, and was characterised by the men employed as bearers as being the easiest to carry of all those they had practised with, though none among them seemed aware of the principle on which this depended. The great stiffness of the stretcher was due to the large sectional area of the side poles combined with their small length, while the weight (only 20 lb.) was not such as to lead to any strong desire to reduce it. The objections to it were that the length (about 5 ft. 8 in.) was too small for many men, and there were at least three separate pieces, the absence of any of which would render it useless, or nearly so.

In designing a stretcher for the British army, the committee were actuated by the following considerations:—(1) That the sacking should be six feet in length; (2) that the stretcher should have as much stiffness as was compatible with moderate weight; (3) that the sacking should be raised from the ground by feet; (4) that the side poles should be capable of being brought together, the feet doubled up, and the whole packed compactly; (5) that every part of the stretcher should be so fixed that it could not be separated or lost. To carry out these objects, the side poles of ash were made square, with the corners above slightly rounded off, with the sides 1¼ in. at the middle, with a transverse section of 3 square in., and to save weight tapering down to 1½ in., or 2¼ square in. section, at the ends of the canvas, beyond which they were rounded off for the better to grasp. Steel traverses, hinged in the centre, and to the poles at the ends, permitted of the poles being brought together or extended as required; and steel feet, hinged so as to close in one direction, but to stand open against a check-piece when extended, completed the arrangement. The stretcher so completed weighed 25½ lb., it afforded a steady bed, though not quite so much so as the French stretcher, and possessed advantages which that did not. On reconsidering the matter, subsequent to the committee making their report, it appeared to me it would have been better to have made the poles of the same dimensions up to the ends of the sacking as they were in the centre; this would have added about 2 lb. to the weight of the stretcher, but would have secured practically as much stiffness as in the French stretcher, and would at the same time have relieved the bearers. This alteration has since been made, and a truck added in place of the steel feet. Stretchers so fitted are now to be seen in the Health Exhibition, and weigh 27 lb.

In the above remarks there has been very little notice of pillows for the stretchers, or slings for the bearers; the committee, however, considered both points fully. As regards pillows, they considered these were unnecessary for the field, inasmuch as every soldier has his great-coat or blanket and valise with him, and if wounded these would have to be carried to the rear with him; either of them can be employed to raise his head as desired, and under such circumstances a pillow, which would add to the weight and bulk and be of little real service, had better be dispensed with. As to slings, these are of two descriptions: that issued to our bearers is a simple leather strap, the middle of which is placed over the back of the neck, and the ends hang down over the upper part of the chest in front, while there are loops at the lower part into which the handles of the stretcher are inserted for carriage. This arrangement, it will be perceived, combines a vertical pull over the front of the chest with a forward pull of the neck, the latter having to be met by a corresponding exertion of the long muscles of the back to retain the head and neck in their proper position, in addition to their doing their portion of the work of steadying the trunk under the vertical pull. Now, this additional exertion simply exhausts the bearer more rapidly than he would be if the forces he has to meet were differently disposed. This can be effected readily by employing what is called the yoke system of sling, which consists of two leather straps, the ends of each of which are fastened together, forming a sort of loop; these are placed one on each shoulder, and the poles of the stretcher are put into the bight of the loops below; a cross piece fixed to each loop just behind the shoulders prevents them slipping off, without causing any drag on the neck at all. The committee recommended that these, and these only, should be issued for use by the stretcher bearers.

Ambulance Waggons.

With ambulance waggons, as with stretchers, mere weight affords but a vague means of ascertaining their relative merits; alterations introduced with a view to improvement often turn out the reverse; and even high commendations by reputed authorities may prove an unsafe basis for an exact estimate of their qualities and of their fitness for rough service in the field. At the Paris Exhibition of 1867 thirteen full-sized ambulance waggons, besides four models, were brought together, including those of the French, English, and American Governments, and prizes were offered to inventors who, after a study of these patterns, and with the permission to adopt any valuable feature they displayed, should construct waggons better fitted for the transport of wounded. Two competitors were successful. Locati of Turin, who produced a waggon embodying some recommendations by Baron Mundy; and Dr. Evans of Paris, who had what was considered an improved form of the Rucker waggon, which had been employed in the United States. On the appointment of the Ambulance Committee in 1868 they applied to have specimens of these waggons placed at their disposal for thorough examination and trial, and at the end of the year they were delivered at Aldershot. Locati's waggon weighed 17 cwt. 2 qr., and had wheels of 33½ and 45½ in., with 1½ in. tyres. Evans's weighed 17 cwt. 1 qr., with wheels of 35½ and 52½ in., with 1¾ in. tyres. The heaviest English waggon in the service at the time weighed 16 cwt. 2 qr. 21 lb.; it was equirotal, wheels 50 in., with 3 in. tyres; its draught was consequently much lighter and much more suited for active service than either of the prize carriages.

In both of the Paris prize waggons it was proposed to carry two persons recumbent in the body, or eight sitting; an average man with his clothing and accoutrements weighs about 150 lb., or rather more than 1½ cwt., and with these numbers the load on the hind springs would vary from 2½ to 10 cwt., in addition to that of the body of the carriage. Now, springs which would act properly with the smaller load would be quite unequal to sustain the greater one; and, *vice versâ*, springs suitable for the greater would act so violently with the lesser ones as to be most injurious to serious cases, as anyone who has travelled over roughish roads in a vehicle with springs insufficiently loaded must have found out. It is usual in this country to meet this difficulty by having a check spring, which comes into action only after the ordinary springs have received their full load, and within certain limits this arrangement is applicable to ambulance waggons, but it is very doubtful whether, even with the check spring, loads varying so much could be carried satisfactorily. Neither Locati's nor Evans's waggon had check springs; and the springs of the former were found so weak at Aldershot that they had to be replaced by a stronger set, and soon after this, with full loads, the body of the waggon settled so much that it bore on the hind wheels, and ultimately tore the spokes out of the naves.

All these waggons, both British and foreign, were fitted with special stretchers, so that a wounded man had to be removed from that on which he was brought to them and transferred to the stretcher belonging to the vehicle itself. It was obviously for the advantage of the wounded that this change should be avoided, and to meet it the Germans had had their ambulance waggons built to receive their ordinary field stretcher—an example followed by the Ambulance Committee in this country. The ordinary track of our military vehicle is 5 ft. 2 in., and with this width the committee found they could have a serviceable waggon with a clear inside breadth of 4 ft. 2 in., which admitted two of the field stretchers, each 1 ft. 11 in. wide, and left space for a partition of 1 in. thick between them, which was carried up sufficiently high to prevent the occupant of one rolling over

Digitized by Google

or incommoding his neighbour from any unusual motion of the waggon.

The object of an ambulance waggon is to transport men who have sustained severe injuries with the least risk or inconvenience; and to effect this they must be subjected to the smallest amount of motion attainable, and in the least hurtful directions. When the springs of both sides of the waggon act equally, at the same time and in the same direction, a vertical motion only results. When the springs of one side only are put in action, they react on the mass above them, causing a heave upwards of that side, with a tendency of the body of the waggon to rotate round a line passing through its centre of gravity longitudinally, and compressing the springs on the opposite side. At the level of the floor this causes a vertical rising motion on the one side and a falling one at the opposite side, while at a variable point between them there is none; at some distance above the floor the vertical component is reduced, and a lateral motion becomes developed largely. In practice, of course, the two modes of action of the springs here mentioned are combined more or less, and varied to infinity by the varying obstacles the wheels encounter, but the motions resulting therefrom are all resolvable into the vertical and lateral components noticed above. If, now, the action of these motions on a person lying on a stretcher be considered, it will be seen that while either rising or falling every part of his body is borne on the stretcher, and all that it is possible to do is to render the transition from either to a state of rest, or to the opposite direction, as soft and gentle as possible by carefully adapting the springs to the load they have to carry. With lateral motions everything is different; there is no support anywhere, and even when the heave is not sufficient to throw the patient to one side of, or even off the stretcher altogether, it causes a rolling motion of the most injurious description for men with serious wounds or fractures; the body rolls from side to side on the chest, and the pelvis and lower extremities follow in the same direction, but at such an interval that the chest has nearly completed its oscillation in the opposite direction before the legs and feet have reached their full swing in the original one. During the Civil War in America, though some of the ambulance waggons were fitted for carrying two tiers of stretchers, the use of the second tier was virtually abandoned.

Locati and Evans introduced springs inside their waggons for the stretchers to rest on, with a view of easing the motion for their occupants, and many others have followed the same practice. All, however, seem to have overlooked the fact that springs, like musical strings, have periods of vibration, varying with their length and thickness, and that to place shorter and lighter springs inside a waggon to lessen the jar of those outside, was, at the same time, to place there a source of movement not in unison with the external springs, and one which this very want of unison could not fail to call into vigorous and, in the case of wounded men or serious medical cases, most injurious action. The committee tried, in the same waggon and at the same time, two stretchers in every respect similar, save that one was fitted with springs while the other was without them, and the difference as regards steadiness in favour of the latter was most marked. From all these considerations it is obvious that a man severely wounded is most advantageously situated where he is subjected to the motion of the body of the waggon alone, at a point as near the floor as can be managed, and the ease of this motion can only be adequately provided for by careful adaptation of the springs to the weight they have to carry.

As already stated, in both Locati's and Evans's waggons, when there were no recumbent cases, men sitting were intended to be carried, but the arrangements for those were far from satisfactory. An ordinary sized man, with a seat of 1 ft. 6 in. in height, requires a space of about 2 ft. 9 in. from his back forwards for the limbs; and if he have to sit for any length of time, it is advisable this should be extended to 3 ft., to admit of greater change of position to relieve the irksome feeling caused by retaining the muscles too long in the same state of tension. If the height of the seat be reduced, it can be made comfortable only by inclining the back, and extending the legs, or, in other words, increasing the horizontal space occupied by the individual. The importance of these points is greatly enhanced when the persons concerned are feverish, or weakened by sickness, for what merely causes irksomeness in healthy men will add much to the suffering of these, and may even aggravate their disease. In Evans's waggon, with seats 1 ft. 2 in. in height, the horizontal space available was only 2 ft. 9 in. at the utmost, and in Locati's, with seats 1 ft. high, the horizontal space was 3 ft., both of them far too small for these heights of seat, while the structure of the vehicles prevented any inclination being given to the back.

There is a strong desire on the part of many persons to have the weight of ambulance waggons largely reduced, without considering fully how far such reduction would affect their durability and usefulness. This question of weight has to be regarded from two points of view—(1) the actual dead weight in the waggon to each person carried, and (2) the manner in which the weight is distributed in the structure itself, and its influence on the draught. As regards dead weight, the Locati waggon, with two recumbent cases, could carry four other persons, including the driver and an attendant, or six in all, with a weight of 329 lb. to each. The Evans waggon, with a similar load, would have a dead weight of 322 lb. to each; and in the heaviest of the English waggons with the same number the dead weight would be 300 lb., but if the number were eight, which the vehicle could carry, it would have been 234 lb. only. In the new pattern ambulance waggon recommended by the committee the weight of the vehicle with all its fittings complete was 18 cwt. 5 lb., and with eight persons, including driver and attendant, the dead weight per man was only 253 lb. With regard to the distribution of the weight, the following facts are of great importance. The waggon of the Ambulance Committee as a whole was 1 qr. 19 lb. heavier than that of Locati, and 3 qr. 5 lb. heavier than Evans's; the body of the vehicle, including axles, springs, and fittings, is lighter than the corresponding parts of Locati's by 1 cwt. 2 qr. 22 lb., and lighter than Evans's by 3 qr. 12 lb. The increase of weight is altogether in the wheels, of which the fore are 36 in. in diameter, the hind 56 in., and both with 2 in. tyres, while they are made of the Madras pattern, with metal naves, which, though heavy, are unequalled as regards strength, suitability for different climates, and facility of repair. The wheels of Evans's, and still more of Locati's waggon, had been reduced, to save weight, until they were no longer serviceable for campaigning, and their draught was most materially enhanced everywhere but on firmly paved streets or roads; and from these an additional hundredweight, or even more, in them would have been a decided advantage for the horses.

It will be borne in mind that the above reflections apply to the ambulance service of troops in the field. In this country, during peace, there can never be the same pressure as after a battle, or with a sickly army, and this will admit of considerable modification of the means employed without material harm accruing. Carriages, too, which are scarcely ever required to move but over paved streets or well-made roads, may prove useful which would tumble to pieces in less than a week in real campaigning, with the rough usage of untrained soldiers; but the principles inculcated, it is believed, are intimately connected with the efficiency of the service everywhere.

THE ETIOLOGY OF TETANUS, AND THE OCCASIONAL VALUE OF NEURECTOMY IN ITS TREATMENT.

BY J. A. MACDOUGALL, M.D., F.R.C.S.ED.,
CONSULTING SURGEON TO THE CUMBERLAND INFIRMARY, ETC.

TETANUS has ever been a subject of deep interest to the surgeon, as much for its mysterious causation as for its terrible and all too frequently fatal manifestations. Well-nigh as often the result of a trivial as of a grave injury, and at times appearing unconnected with any traumatism, it is no wonder that since pathology became the science it is to-day, its best efforts should have been devoted to the discovery, if possible, of the morbid conditions which mark a disease, some of the strongest features in which are that the widest and ripest experience may entirely fail to apprehend its advent, to explain why it should have appeared, or to predict with any certainty the anatomical changes which underlie it. And even now the task is unaccomplished, for, great as the progress has been in the demonstration and elucidation of the morbid anatomy of the spinal cord, there yet remains a hiatus in our knowledge as to any one condi-

Digitized by Google

tion which may be regarded as characteristically *the* lesion of tetanus. Lockhart Clarke, Dickinson, Allbutt, and Coats, investigators whose knowledge of spinal pathology was and is transcendent, have each described certain appearances which they are inclined to regard as necessarily associated with the disease; but other observers equally earnest, and we believe equally careful, have failed entirely to corroborate their results. Nor are we inclined to regard this as extraordinary, for it seems to our thinking that it would be indeed difficult to understand, were the marked changes they have described always to exist, how such complete relief of symptoms and rapid recovery could have followed as has undoubtedly obtained in certain cases treated by neurectomy and by amputation. It almost appears as if this very search for morbid lesions, and the descriptions given of them by the observers to whom I have already made reference, had, in that necessary questioning which has arisen as to their probable causation, turned the attention of the profession so thoroughly to the humoral pathology of tetanus that its members seem in danger of forgetting the possibility that an excentric irritation may at times play a very important part in the origin of the disease. Before, however, entering upon the cases which I mean to detail in support of this last proposition, I desire to consider shortly the usually accepted theories of its causation — the humoral and the nervous,—and the reasons adduced in their support.

Dr. W. B. Richardson's opinion, expressed many years ago, was that the disease depended upon a poison developed in the wound as a result of decomposition; and this view has been sustained by the recent investigations of Coats,[1] who believes that the special changes observed by him in the spinal cord are the secondary effects of a *materies morbi* which, circulating in the blood, acts primarily upon the bloodvessels themselves. Certain etiological and vital conditions are admittedly strongly in favour of such a view; the occurrence of idiopathic tetanus seems difficult of explanation upon any other supposition than that of an alteration in the blood itself; and yet so intimately associated is the bulk of such cases with certain climatic conditions, the presence usually of damp and cold, that I would incline to the belief that in some of them we may have in their atmospheric surroundings the sources of peripheral excitation. Mirbeck[2] cites a case of an infant who died of tetanus four days after having received full upon its chest a glass of iced water while in a state of perspiration; and the fact is well established that by chilling a healthy nerve with ice its condition is so changed that the least tap upon it brings about violent and sudden spasm. Baron Larrey states that in a case of acute tetanus in which amputation was resorted to, and in which the symptoms entirely disappeared, the patient having been unhappily exposed to the chill air of night, immediate and fatal relapse followed. Tetanus is not uncommon in the horse as a direct and rapid sequel of "clipping" done in very cold weather, and in aged animals it is not unfrequent after exposure to storms of snow and cold winds. It seems, then, that if a comparatively limited shock from cold is capable, as in the case of the child it proved to be, or, by a more general impression, as in the horse, of originating the disease; if it exercise, as it surely does, so strong an influence on nervous tissue; and if, as probably occurred in Larrey's case, the irritation of the cut nerves in the face of the cut stump reproduced it,—then we can believe that in some individuals it may be the direct result of excitation arising from the exposure of surfaces rich in nervous supply to the chilling effects of damp and cold.

Nor is tetanus the only disease which is rendered more common by certain atmospheric conditions. Many authorities in midwifery state that puerperal eclampsia is similarly influenced, and as this is a condition not always due to the existence of a poison in the blood, it is probable that in the nervous system itself the phenomena which mark it have primary origin.[3] The occurrence of tetanus in an epidemic form, and its direct association with bad hygienic surroundings, are to my thinking the most powerful of all arguments against the nervous theory; and yet even here one must consider how much the lowering of nerve-tone, which is ever the outcome of such conditions, may have to do in predisposing to its development a patient whose nervous system, either as the result of traumatism or atmospheric conditions, has been subjected to peripheral irritation. The rise in temperature usually observed in septic states has been pointed to as an indication of change in the blood, but this is by no means certainly present in cases of tetanus; indeed, I have seen a case run rapidly to a fatal termination with scarcely any rise in temperature, such rise as did occur being perhaps explicable as the result of severe convulsions in a man whose nervous system was for the time being in an extraordinary state of instability. The testimony of O'Beirne[4] is on this point of interest, for although he had necessarily no knowledge of clinical thermometry, he doubtless possessed the power of recognising the febrile state, and yet he notes that in 200 cases he witnessed in the Peninsula none were febrile. Of moment as a prognostic sign, for a high temperature in tetanus indicates as a rule a severe form of the disease, it is yet no positive indication that a poison is circulating in the blood. Trismus nascentium, the pathology of which has been long in dispute, but which in later times has been accepted very widely as a well-marked instance of zymosis, has received from different quarters fresh questionings as to the truth of the doctrine. The first and much the earlier is that of Marion Sims, who asserts that it is "a disease of centric origin depending upon a mechanical pressure exerted on the medulla oblongata and its nerves; that this pressure is the result most generally of an inward displacement of the occipital bone, often very perceptible, but sometimes so slight as to be detected with difficulty." After viewing the disease in all its bearings one has difficulty in accepting such an explanation; but Dr. Hartigan,[5] who has made 150 post-mortem examinations in such cases, records his experience as entirely in accord with Sims' views. But there is another authority, Parrot, who has, according to the thinking of Nicaise, demonstrated that in temperate climates at least the disease, which has been described as trismus nascentium, is only a form of eclampsia due to uræmic brain disease;[6] and in support of this there is the recognised fact that its symptoms differ in some important particulars from those of true tetanus. Attention, too, has been drawn to an unhealthy state of the wound as a possible cause of tetanus, and in many recorded cases there existed such a condition; but its importance diminishes when we remember the fact that tetanus may occur with wounds which are perfectly aseptic, or appear when the primary injury has soundly and completely healed. As the result, however, of careful consideration of the arguments in its favour, and the objections which may be urged against them, there yet remains a seemingly insuperable difficulty in explaining upon any other grounds than those of a dyscrasia many cases marked by all the impressive features of tetanus. That a certain number of cases are due to direct nerve irritation is my belief, and, great as the difficulties are in demonstrating or explaining scientifically how peripheral irritation can excite and keep alive the widespread series of phenomena which characterise the disease under consideration, there are, I submit, a sufficient number of cases on record in which section of nerves has cured it to warrant the belief in a *post et propter hoc*.

There is one fact which must strike all interested in cases of tetanus, that in the mass of tetanic histories the irritation which we contend has arisen is connected with the extreme distribution of nerves. Not only so, but injuries in certain localities are notably more liable to be followed by it, and in some of these regions, as in the instance of the fingers and hand, the tactile corpuscles of Meissner and of Pacini are most abundantly developed. In my own experience of the disease nearly two-thirds of the cases had sustained injuries of the hands or feet, and in a very considerable number of instances which I have collected in the practice of my professional friends more than half were connected with wounds of the upper extremity. That these facts are not mere coincidences I feel well assured, and I believe they admit of a solution which may have some bearing in explaining one possible mode of origin of the disease. It is within our knowledge that as nerves approach the cutaneous surface, and especially when they enter the region of the skin, they lose their protective coverings, the medullary sheath and the sheath of Schwann. They are, therefore, especially exposed to injury and to irritation; and so much importance would I incline to attach to this circumstance, that I would venture to guess that the very presence of these sheaths and the protection they afford to the enclosed axis cylinder mainly accounts for the observation that injuries to large nerves in their course are not so pro-

dustive of tetanus as when in their distribution they have reached the periphery. The experiments of Brown-Séquard,[7] performed long ago, proved the fact that irritation applied to the cutaneous ramifications of certain nerves induced convulsions, while irritation of their trunks had no such power; and Weir Mitchell, in his valuable monograph on "Injuries of Nerves,"[8] remarks "that the tendency towards irritation, resulting in spasm, seems to increase as the nerves divide and approach the skin." Mitchell Banks, in the Liverpool Medical and Surgical Reports for 1869, details some cases of slight injuries to digital nerves, giving rise to distressing symptoms and widespread reflex sympathies, while the cases detailed by Swan in connexion with lancet wounds of nerves would lead one strongly to suspect that wider reflex symptoms are likely to be aroused by wounds of small cutaneous nerves than by those of larger and more important trunks. But the difficulty lies not so much in finding the probable source from which the irritation springs as in explaining in what way it induces tetanic symptoms. The theory that would explain its occurrence in every case as due to an ascending neuritis cannot be accepted, for the evidence pathology can offer is clearly against it, but that reflex symptoms may arise independently of any inflammatory condition is proved by the cases of Banks, to which I have already made reference, for not only in them were portions of the affected nerves removed with excellent results, but the most careful examination failed to detect any morbid change in the parts removed. That neuritis does occur in some cases, and that without the presence of an open wound, I have personal knowledge, for in the very last case of tetanus which came under my observation, where it followed extraction of a tooth within twelve hours of the operation, and where death occurred in little more than thirty hours from the seizure, the inferior maxillary nerve was hard and red, and was by careful examination demonstrated to be in an undoubtedly inflamed condition. Moreover, the presence of pain and tenderness in the line of the nerves of the extremity involved in an injury of which records exist seems to warrant the conclusion that in such cases there is present a more or less developed neuritis. Independently, however, of any such direct transmission of harm, it seems to me, arguing from other morbid states than that of tetanus, that in certain individuals—for I believe there is a personal equation in most tetanic cases—it is possible for a peripheral irritation to induce exaggerated spinal reflex excitability, or direct reflex excitation either, as has been supposed, by paralysis of the moderator centre for reflex action or by Ringer's ingenious theory of lessened resistance.

In two other nervous maladies have we symptoms somewhat similar in their manifestations, and I believe equally difficult as regards their *rationale* of scientific explanation. Epilepsy, no longer regarded as a blood disease in the sense that Dr. R. B. Todd held it, is now considered to have its probable seat in the middle motor region of the cerebrum. Several cases are on record where irritation of a particular cutaneous region induced attacks of this malady. Dieffenbach details a case cured by the removal of a bit of glass lying in close proximity to a nerve; Pouteau cured the affection by destruction of a painful cicatrix; Carron by the removal of a tumour on the thumb; Bryant by an incision through a tender spot on the scalp; while Brown-Séquard states that "we know many cases where there was in the beginning of the fits a local cramp resulting from a secondary irritation of the nervous centre—i.e., produced by a reflex action due to excitation of sensitive nerves near the muscles attacked with cramp."[9]

And again, chorea, the morbid anatomy of which is still unwritten, has, in some instances, the most intimate connexion with excentric irritation. Packard, in the *American Journal of Medical Science* of April, 1870, records a case arising from injury to the terminal end of the median nerve in the thumb, which was cured by exsection of the sensitive part; while Weir Mitchell,[10] writing of it in connexion with wounds of nerves, and especially in association with the changes which take place in the divided ends of nerves in stumps, says, "The stump muscles or nerves are in the condition of those of a person fully charged with strychnia, ready to respond excessively, and without regularity, to any excitation." If, then, epilepsy and chorea, diseases having their seat in higher centres than those affected in tetanus, can be the result of irritation in the ultimate distribution of nerves, then it seems more easy to receive without sufficient or adequate explanation the possibility that tetanic spasms may arise in a similar way, and thus we escape the necessity, which many seem inclined to accept, that only through a poison in the blood can tetanus be produced.

One fact among a very considerable number that is difficult of explanation on the sepsis theory is the *rationale* of the cause of death in such cases as those recorded by Bandelaben and Robinson, where it followed in a quarter of an hour from the time of the receipt of the injury. Severe nervous excitation sufficient to upset the working of some highly sensitive and delicate nerve centre, the outcome of which was a suffocative spasm, might produce this. It is certainly well nigh impossible to conceive a poison generated *de novo* in the wound capable of development and of such momentous action in so short a period. Further, the disease has never been transmitted by inoculation or transfusion; while the kindred states, to which as regards physical manifestations it is often likened, hydrophobia and strychnia poisoning, are but too readily propagated by the transference of the blood in which the poison is circulating.

(To be concluded.)

A NEW INHALER.

WITH REMARKS ON OPEN ANTISEPTIC INHALATION.

BY J. WARD COUSINS, M.D. LOND., F.R.C.S.,
SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

THE discovery of Koch's bacilli amid the morbid processes which are now grouped together under the term pulmonary phthisis, and the new theory grafted upon it, that micro-organisms are the essential elements in the development of tubercular disease, have certainly stimulated the revival of the old treatment by inhalation, and have stamped it with fresh value and importance. It is, however, a matter for pathological investigation to unravel what is the exact relation between these specific bacilli and the pneumonic changes which pass on to softening and excavation; and whether the organisms are to be regarded as the cause or the mere outcome of these necrotic processes. At present we are not warranted in assuming that phthisis is the product of a distinctive bacillus embedded in the tissue of the lung, and we must wait for the results of future investigation and experiment; still the progress of research clearly points to the conclusion that phthisis, with its many variations, will soon be recognised as a specific disease, characterised by the formation of a new growth, containing specific micro-organisms, which can be detected in the sputum during life, and in the structures invaded by the disease after death.

Now, there is some subtle association between this modern theory and the fashionable treatment of inhalation which appears to be almost anticipating its final demonstration. But it must be stripped of all speculative value, and the test of experience alone must be the real guide for its adoption. The notion that antiseptic vapours are weapons of destruction upon these mysterious organic forms may seem a hopeful creation of the imagination, but certainly there is not a fragment of evidence even to suggest the assumption that volatile antiseptics are killers of bacterial growth hidden in the substance of the lung. Moreover, it is not possible to conceive how either dry or moist vapours in any form, possessing a low degree of volatility—whether administered by the aid of respirators, or by immersion in the atmosphere of a chamber charged with the most powerful medicinal substances—can ever be sufficient in potentiality to arrest within the pulmonary tissue the development of the specific organisms which are found to be intimately associated with the existence of tubercle.

The recent revival of the old question as to the contagiousness of phthisis has also exercised an important influence in promoting the treatment by inhalation, and has even succeeded in giving it a new direction. The possible communication of the disease by contagion of some sort has long been a matter of controversy, and many men of distinction have taken part in this ancient disputation; but at the present moment it is still surrounded by many difficulties, and it

Digitized by Google

appears almost as far off as ever from a final settlement. The discovery of micro-organisms has produced a complete resuscitation of the old dispute, and has surrounded it with new and impressive issues. Some regard the results obtained by the inoculation and artificial cultivation of the specific bacillus as strong evidence in favour of the doctrine, and their convictions on the matter induce them to advocate a special method of applying topical remedies to the air-passages. The speculations concerning the existence of the bacillus in the phthisical breath and the dissemination of its germs in the air, mingled with the germs of universal distribution, are far beyond the limits hitherto reached by scientific research. Yet the mere conjecture that germs may find an entrance from without has certainly roused the ingenuity of some inventive minds, and suggested to them the grave necessity of intercepting them by a mechanical device at the very threshold. It is in this way, too often, that enthusiasm develops theory, and theory wields a directing force in the construction of methods of treatment which are utterly inconsistent with scientific truth, and even common experience. Surely it is a fact beyond dispute that no kind of inhaling contrivance can defy the entrance of germs with the air of inspiration; at the same time no form of respirator can be persistently employed by the patient. In reality it is a mere fad to attempt to filter and sterilise the air, for there is not a particle of evidence to support the notion that such filtration can be essential to the successful application of inhalations in those individuals who are actually labouring under tubercular disease, and it is extremely improbable that any laborious endeavour to sterilise the air can help to check the growth of organisms which have already found a lodgment in the lung. Even admitting that it is possible, by the intermittent application of a complex cover over the mouth and nose, to reduce the number of infective particles which enter the body, and to isolate, in a measure, the patient from the invisible hosts around him, then it clearly follows that such device ought to be considered in the light of a protecting instrument for any individual threatened with pulmonary disease, who is unfortunately exposed by social circumstances to the danger of a pollnted atmosphere, by contact with others actually labouring under phthisis, and, therefore, the disseminators of an infective material which is capable of impregnating the organs of any susceptible of its invasion.

On the other hand, I am not singular in holding the opinion that all efforts to filter the inspired air are theoretically unsound and practically useless, and that the cumbrous instruments constructed with this intention often indirectly exercise a baneful influence on the surroundings of many who are daily endeavouring to protect their lungs with antiseptic inhalations. The constant use of a close inhaler fosters the common prejudice against fresh air and sufficient ventilation, and the treatment degenerates into a struggle between germs within and germs without, hopelessly carried on by breathing through an uncomely mask, and by confinement in a close and stuffy atmosphere. I feel convinced that every remedial agent employed in the management of chest disorders must be positively injurious to the patient whenever it distracts the attention from the common and hygienic measures which are so essential to the general improvement of the system and the increase of the vital resistance of the whole organisation.

Now, in whatever light the speculations are regarded concerning the action of inhalations as destroyers of bacilli or as protectors against floating germs, it must be admitted that this treatment has made remarkable progress, and has also been practised with very great success. What, then, is the *modus operandi* of antiseptic inhalations in pulmonary affections? Surely the action of these remedies admits of a very simple explanation. They are valuable not only in the treatment of phthisis in all its forms, but, fortunately, they are equally applicable for many other chronic disorders of the lungs, and their judicious administration is certainly followed by very considerable relief. Dr. Solomon Smith[1] observes: "We are forced to believe that the benefits derived from the use of antiseptic inhalations are due to the infiltration of the lungs with antiseptic material, rather than to any action upon the floating germs." The vapours which are mingled with the inspired air penetrate to the finer passages, and are there absorbed by the moisture of the respiratory surface; and thus, by direct application, they purify the air in the remote portions of the lungs and cleanse the mucous membrane generally by preventing decomposition in the fluids and stimulating more healthy secretion. In chronic bronchitis, bronchorrhœa with dilated bronchi, and emphysematous affections, the efficacy of the treatment is beyond dispute; for by assisting the discharge of the expectoration, and by delaying the septic changes which occur within it, they remarkably modify the disorder at the very seat of its activity. In phthisis these topical remedies have proved also powerful auxiliaries to general treatment. They check decomposition in the secretions, and aid in the evacuation of the infectious materials, which are the direct products of the disintegration of the pulmonary tissues, and which, by the processes of absorption and diffusion, often establish new centres of disease. But, apart altogether from any specific effect of the antiseptic vapours, it must be admitted that the act of continuous inhalation exerts a very salutary influence by stimulating full and repeated expansion of the lungs; and this forced activity of these organs is in itself an important factor of the treatment. The value of free inspiration, and the part it plays in the successful application of antiseptic inhalation, have scarcely received the general recognition to which they are justly entitled. Many years ago the late Dr. Ramadge warmly advocated the use of an inflating tube for the simple purpose of expanding the lungs and stimulating their functional activity by voluntary effort. In phthisis these organs are very imperfectly expanded. The sputa, collecting in the passages, obstruct the aerial movements, and some portion of the air, only partially changed, becomes imprisoned in the remote parts of the pulmonary tissue, and thus the healthy balance between inspiration and expiration is disturbed, the breathing becomes shallow, at the same time gradual contraction and emaciation of the thoracic parietes are seriously accelerated. Now, it appears to me that much of the success which has followed the introduction of antiseptic inhalation is due to persistent expansion of the lungs by forced inspiration, and, certainly, this novel and fashionable system corroborates the value of the mechanical method practised by Dr. Ramadge. His notions respecting the antagonism between emphysema and phthisis have now almost passed into oblivion, but his special treatment of utilising functional activity as an instrument for arresting the progress of tubercular disease is surely now receiving a remarkable acknowledgment in the revival of respirators and local medication. The new treatment is, in fact, a close repetition of the old mode of inflation, with the addition of an antiseptic vapour to the inspired air; and the beneficial effect produced by its persistent employment can in a great part at least be fairly attributed to the expansion of the chest in full and forced inspiration, for this not only assists in maintaining the volume of the lungs, and in stimulating the activity of those portions of their structure still free from the elements of tubercle, but it also favours the circulation itself, and helps on the processes of local and general nutrition, by which a vital resistance is developed, restraining the progress of the disorder, and powerfully contributing towards its final arrest through the contraction and limitation of the local disease.

The advocates of antiseptic inhalation are quite unanimous as to the necessity of employing it with great regularity and perseverance over a long period; but there is much diversity of opinion as to the method of application and the form of instrument best adapted for the treatment. Recently Dr. Hassall has referred to "the comparative inefficiency in diseases of the lungs of the methods of inhalation now in use by means of oral and oro-nasal inhalers," and he advocates the revival of the old method of treatment by means of a chamber charged with antiseptic vapours, and is now engaged in perfecting an apparatus which he hopes will render this system more generally practicable. The experience of most practitioners at the present time is, however, clearly in favour of the direct inhalation of dry vapours, and a great variety of instruments have been constructed for the purpose—for the most part modifications of the original respirator inhaler suggested by Dr. Sinclair Coghill in 1876. The simplest forms of apparatus are now almost universally preferred, as they are more comfortable to the patient, and more readily tolerated during prolonged application. Some inhalers are too heavy and cause a feeling of oppression, and sometimes even difficulty of breathing; others are objectionable by pressing on the face and causing irritation of the skin. It is my opinion that all close oro-nasal respirators

[1] Vide British Medical Journal, Feb. 23rd, 1884.

Digitized by Google

and complex instruments present no real advantages, and that they must soon fall into disuse, as their employment is seriously irksome to many patients. An inhaler ought to be a very light mechanical contrivance, especially designed to permit the voluntary introduction of medicated vapour by full inspiration, at the same time securing the freest possible access of air, so that the continuous and daily practice may be rendered both endurable and pleasant. The small instrument represented in the engraving appears to me to possess all these essential qualifications. It consists of a vulcanite receptacle (see Fig. 1) for holding the little pledget of cotton-wool upon which the inhalant is dropped. The

FIG. 1.

FIG. 2.

wire suspends the inhaler, and serves also as a compressor of the nose. When used for nasal inhalation one of the balls (see Fig. 2) must be selected, and half only of its circumference ought to enter the nostril. During oral inhalation another ball is used, or the neck of the inhaler can rest against the upper teeth. Figures 3 and 4

FIG. 3.

FIG. 4.

explain the methods of adjusting the instrument. By merely opening and closing the mouth the patient can regulate the entrance of the antiseptic vapour into the lungs. It is extremely light, and causes no fatigue or oppression, and it does not require to be taken off during coughing and expulsion of the sputa. I am much indebted to Messrs. S. Maw, Son, & Thompson for the care they have bestowed upon the manufacture of my inhaler, and I am glad to add that it can be obtained from that firm at a very moderate price.

The following table exhibits the respective weights of some of the best known inhalers now in general use :—

	Drachms.	Grs.
Coghill's metal inhaler	8	45
,, nickel-plated inhaler ...	7	19
,, celluloid ,, ...	3	27
Mackenzie's metal ,, ...	15	40
,, nickel-plated ,, ...	18	52
,, celluloid ,, ...	8	29
Robert's nickel-plated ,, ...	9	3
,, metal ,, ...	7	2
Burney Yeo's perforated zinc inhaler	3	40
Ward Cousins' inhaler	1	12

In conclusion, it has been my endeavour to confine this paper strictly to the consideration of open inhalation; and I have ventured to suggest that it is not merely a convenient mode of employing the breath as a medium for the introduction of antiseptic vapour, but that it is also a simple and mechanical method of sustaining forced inspiration, and thus utilising the antagonism which fortunately exists between pathological change and healthy activity. Any reference to the value of different inhalants and antiseptic combinations has been intentionally avoided, and for information on these important matters I must especially mention the paper of Dr. Sinclair Coghill,[2] and also many recent contributions by Dr. Burney Yeo, and other eminent physicians. To Dr. Sinclair Coghill we are undoubtedly indebted for the revival of inhalation as a regular part of the treatment of pulmonary disease, and a perusal of his published experiences will be extremely serviceable to any who have not yet given it the attention which it merits.

Southsea.

A CASE OF NASO-PHARYNGEAL POLYPUS;

REMOVAL BY THE ÉCRASEUR AND ACTUAL CAUTERY, AFTER SPLITTING THE SOFT AND CUTTING AWAY THE POSTERIOR THIRD OF THE HARD PALATE.

By W. J. WALSHAM, F.R.C.S.,

ASSISTANT-SURGEON TO, AND DEMONSTRATOR OF ORTHOPÆDIC AND PRACTICAL SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL.

W. B——, aged forty, a maltster, was admitted, under my care, into Pitcairn ward, on Jan. 1st, 1884, having for some weeks previously been an out-patient. He complained of a stoppage of the right nostril, attended with a discharge from both nostrils, which at times was blood-stained. He had also severe and continued frontal headache, and frequent pains, darting from the nose to the right ear. He stated that about nine months ago he had been taken ill with bronchitis, and was treated for it at Victoria-park Hospital, where he was told he had weak lungs. Since then he had lost twenty-eight pounds in weight. The obstruction of the right nostril had come on gradually, and he was now unable either to blow or breathe through it. The discharge, which was often offensive, at times passed down his throat, and was brought up on coughing. He had always been a temperate man, and had hitherto enjoyed excellent health, and there was no history of cancer or syphilis.

Nothing abnormal could be seen on examining the nose through the anterior nares, even with the aid of a long Zaufal's speculum. It was found, however, on attempting to pass a small indiarubber tube for the purpose of tying up the palate, that the right nasal cavity was blocked posteriorly. On introducing the mirror behind the palate tied forward by the indiarubber tube, which was easily passed through the left nostril, a large swelling in the naso-pharynx on the right side was made out, and could also be felt with the finger carried behind the palate. Manipulation with the finger caused excessive hæmorrhage, although it was done with all gentleness, the patient losing more than half a pint of blood. A small gland could be felt just behind the angle of the jaw on the right side, and one or two smaller glands on the left side of the neck, posterior to the sterno-mastoid muscle. On Jan. 8th the growth was found to have markedly increased in size, and although its exact attachments could not be made out either by posterior rhinoscopy or with the finger, it was thought that it sprang from the basilar process, and probably also from the posterior wall of the pharynx. It was resolved to attempt its removal.

On Jan. 12th, the patient having been placed under chloroform, two silk sutures were passed through the soft palate, one on either side of the middle line, and the soft palate divided to its junction with the hard. The incision having been carried forward in the middle line for about an inch and a half, the soft tissues were separated from the bone with the aid of raspatories, and having been held aside with silk sutures, the posterior third of the hard palate was cut away with a mallet and chisel. An excellent view of the parts was now obtained, and the stem of an écraseur was passed through the right nostril, and the cord guided round the growth with the aid of the finger in the pharynx. It was found that the growth had a more considerable attachment to the posterior wall than was imagined, and it had to be torn and raised with the finger so as to form a groove for the cord of the écraseur. On screwing up the écraseur the greater part of the growth was in this way removed, and what remained of its base was destroyed with a Paquelin's benzoline cautery. The palate was then brought together and united with horse-hair and silver sutures in the ordinary way. The operation lasted upwards of an hour, and a considerable amount of blood was lost from the great vascularity of the growth, and

[2] British Medical Journal, May, 1881.

Digitized by Google

its tendency to bleed on even the gentlest manipulation. The growth removed was about the size of a small orange. It was tough, hard, and fibrous in consistency, of a yellowish-white, shining appearance on section, and, as was seen on microscopical examination, was composed of fibrous tissue with an admixture of spindle-shaped cells. On the 13th he passed a fair night. The evening temperature was 100°, but in the morning it was again normal. There was great pain in the head. The nose was ordered to be syringed out every two hours with weak Condy's lotion. On the 20th the sutures were removed from the palate. On the 22nd he was up for the first time, and on the 31st he was discharged from the hospital breathing freely through the right nostril, and well in every respect. The gland at the angle of the jaw was much smaller. On March 4th the patient was readmitted, as the gland had increased in size, and others had appeared. These were removed on March 6th, and the naso-pharynx was thoroughly examined whilst under chloroform. Some induration was felt at the former situation of the growth, but there were no definite signs of a return. The wound of the neck healed readily, and the patient left the hospital on March 20th.

Remarks. — The severe hæmorrhage which attended even the most gentle examination with the finger made it exceedingly difficult to define the exact attachments of the growth, and its size was such that the rhinoscope revealed little more than that there was a large mass blocking the right choana, and occupying the right half of the naso-pharynx. It became a question therefore what operation, if any, should be attempted for its removal. It was clear that, from its size and attachments, it could not be removed through either of the natural passages—i.e., anteriorly through the nostril or posteriorly through the mouth; and for the same reasons the operation of turning up the ala of the nose, or that of Rouge, did not commend themselves. The choice of operation was therefore narrowed to that of the partial or complete removal of the superior maxilla, or splitting the palate after the method of Nélaton. The last, as attended with the least danger, was finally decided on. A better view of the parts could not have been wished for, and although the removal of the growth was still difficult on account of its broad base of attachment, the whole of it was ultimately removed. The patient made an excellent recovery. The temperature, which never rose above 100·6°, fell to normal on the fourth day, and so remained for the rest of his stay in the hospital. The growth, though hard, firm, and apparently fibrous, was found on microscopical examination to be a spindle-celled sarcoma, and it is therefore interesting to note the secondary affection of the glands in the neck. The superiority of Nélaton's method of splitting the palate, over Langenbeck's operation of resection of the maxilla for the removal of such naso-pharyngeal polypi as do not allow of extirpation by simpler methods, cannot, I think, be too strongly insisted upon; and the more so as it does not appear to be generally admitted. I have seen both, and have no hesitation in preferring the former. The one is comparatively speaking a slight, the other a most serious, undertaking; in one there is but little shock, in the other it is severe; in one there is next to no hæmorrhage, in the other it is free, sometimes alarming. The latter, moreover, leaves an external scar, is necessarily attended with some injury to the lacrymal apparatus, and may be followed by unsightly œdema of the lower eyelid. In both an excellent exposure is obtained, but I do not think that that in Langenbeck's operation is any better for the purpose than that in Nélaton's. When the growth has invaded the anterior part of the nasal fossæ or the antrum, no doubt resection of the maxilla is the better operation; but when it is confined to the posterior third of the nasal fossæ, Nélaton's in my opinion should be performed, and it is principally for the purpose of calling attention to this point that the case is published.

Wigmore-street, W.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.

At the meeting of the committee of management of this institution, held on the 5th inst., Dr. Robertson stated that during the half year ending June 30th, 1102 in-patients were admitted to the hospital. Of these, 684 were discharged as improved, 127 as no better, 6 at their own request, 8 were dismissed, 4 died, and 278 remained on the books at the end of the half year. The number of out-patients admitted was 91, and of these 26 remained on the books.

A CASE OF CEREBRAL EMBOLISM WITH HYPERPYREXIA FOLLOWING CHILDBIRTH;

WITH POST-MORTEM APPEARANCES AND REMARKS.

BY ERNEST F. NEVE, M.B.ED., M.R.C.S.,
RESIDENT PHYSICIAN TO THE COWGATE DISPENSARY, EDINBURGH.

MRS. F——, aged about thirty-seven, multipara, consulted me on Feb. 20th, 1883, for considerable uterine hæmorrhage, from which she had suffered on the previous day. She was eight months pregnant. Palliative measures were adopted with success. On March 22nd hæmorrhage recurred, and continued in spite of treatment. Having diagnosed partial placenta prævia, I introduced a sponge tent. The hæmorrhage ceased, and she slept fairly well during the night. The following morning, however, on removing the tent, bleeding recommenced. I then ruptured the membranes, and with the aid of Barnes's bags dilated the os uteri to the size of an orange. Dr. Underhill, for whom I now sent, at once proceeded to perform bipolar version. The contractions of the uterus proving, however, a serious obstacle, the child did not survive.—24th: The patient had not slept at all. Great after-pains; weakness of both legs. Free lochial discharge; transverse colon greatly distended with flatus; pain in the hypogastric region. Temperature 98·4° F.; pulse 78, slightly dicrotic. — 25th: Had passed a quiet night. Lochia had a slightly fetid smell. Pain and swelling of the lymphatic glands at the inside of the right thigh. Temperature 101°.—26th to 30th: Still complaining of weakness in both legs. The pain in the groin and hypogastric region less. Lochia diminished and with less odour; spirits better. A tendency to diarrhœa. Temperature never found to be above 100°.—April 1st: Depression of spirits; complaining of a slight cough, about which she was very nervous. Legs still weak, with pain in the groins on movement. Temperature 101°. During this time milk diet was adopted, with the addition of concentrated soups and small quantities of wine at regular intervals. For the pain and elevation of temperature Battley's solution, sulphate of quinine, and turpentine stupes were employed.—2nd: Patient nervous and anxious; cough more frequent. Slight cold sensations in the back; no physical evidence of pneumonia. Temperature 103·4°. I was sent for suddenly in the evening, and on arriving was told that as she was sitting up to take her medicine she fell back and became insensible. I found her quite unconscious, with paralysis of the left side of the body and clonic spasms of the right. The movement of the right arm was circumduction at the shoulder-joint forwards and from within outwards. The foot was alternately flexed and extended. Eyes open; pupils contracted and equal. Mouth open; tongue and lips dry; cheeks flapping slightly with the respiration, which was stertorous. Temperature 105·4°; pulse rapid, weak, and jerking (106). Sulphate of quinine in fifteen-grain doses was exhibited at frequent intervals. Sinapisms over the chest, and the cold douche applied from a height above the head did not restore consciousness. The hair was cut and cold water compresses applied to the head during the night.—3rd: Both arms and legs motionless and flaccid. Right pupil much dilated; left pupil moderately contracted. Respiration stertorous (40); pulse 125; temperature (tested in both axillæ with two thermometers and observation repeated) 106°. Ice was applied to the head, and an enema of quinine administered. The patient died at 11 A.M.

Necropsy, twenty-five hours after death.—Gas was seen bubbling up from the nostrils and mouth. Pupil of right eye slightly dilated, and the cornea unusually bright. Rigidity well marked in lower extremities; lividity slight. Abdomen very greatly distended with gas. Brain: Superior longitudinal sinus contained a long decolourised post-mortem clot. The vessels of the vertex injected with dark fluid blood, and their terminations distended with gas. An excess of subarachnoid fluid, which was turbid; vessels of pia mater injected. The internal carotid artery of the right side, immediately below and at the origin of the posterior communicating branch, was completely closed by a firm pale ante-mortem clot. The basilar artery contained three small cream-coloured clots from ¼ to ½ in. long, with rounded ends. These were not impacted, and may have been of post-mortem formation. The cere-

Digitized by Google

bral substance was injected. Both lateral ventricles contained a small quantity of blood-stained fluid. There was no evidence of anæmia of the right hemisphere. Brain tissue very soft. Heart: Flaccid; almost empty. Endocardium stained very darkly, valves being plum-coloured. The anterior internal aortic valve presented on the ventricular surface a small dark clot, which on removal disclosed a slight roughening of the endocardium. The inner surface of the left ventricle presented a marbled appearance. Spleen: Measured 7 in. by 4 in., very soft. Lungs: Pleural cavities contained no fluid. Both organs very soft, highly congested, with œdematous bases. No consolidation. Bronchial mucous membrane reddened and softened. Liver: Congested and fatty. Kidneys: Both very soft and greatly congested. Stomach and intestines greatly distended with gas; no evidence of peritonitis. Uterus measured 6 in. by 4 in. Ligaments thickened; no evidence of cellulitis. The interior, which had a fetid smell, presented a slate-grey appearance. At the placental site there were two depressed patches measuring respectively ½ in. by 1½ in., with rough granular floor of ash-grey colour; ovaries large and congested. Microscopically the clot from the internal carotid artery showed almost throughout the outlines of the individual corpuscles. It was adherent to the walls of the vessel by granular débris, fibrin, &c.; muscular fibres from the heart were cloudy and fatty. In the lungs some of the air vesicles showed evidence of croupous exudation. There was no thrombosis of the pulmonary veins. Kidneys: Epithelium of tubules greatly swollen, cloudy, and desquamating. Uterus (from the placental site): The inner surface presented the appearance of a false membrane composed of fibrin, leucocytes, compound granular corpuscles, and granular débris. In the kidneys and uterus there were some highly refractile bodies, giving no reaction with osmic acid solution, and not unlike micrococci.

Remarks.—References to the state of the body temperature after the occurrence of cerebral embolism are omitted in most text-books of medicine. According to the observations of early writers, especially Cohn, it was formerly believed that following embolic impaction there was both an initial and, for a time, a permanent general diminution of the temperature of the body. Bourneville's observations, on the other hand, have shown that there is a rise (reaching in some cases even 104°) on the second and third days and then a rapid fall.[1] Dr. Hamilton[2] quotes a case of Sokolowski's in which the temperature on the first day was 101·2°, and the next evening 104·8°. In this case, however, there was acute endocarditis. In a case of his own in which embolism occurred during the resolution stage of croupous pneumonia, the temperature was not high till the second day, when it reached 104°. I have, however, been unable to find any case on record in which there was hyperpyrexia. The pulse and respiration of Mrs. F——, contrary to the observations of M. Rosenthal,[3] were found to be both of them unusually rapid. It is, I believe, rare for a case of cerebral embolism to prove fatal within twenty-four hours. It appears to me, therefore, highly probable that the hyperpyrexia was the cause of the anomalies in, and the rapidly fatal issue of, this case. The question next arises as to its origin. The clinical history, especially as regards the persistent elevation of temperature, its steady rise immediately before, at the time of, and after the embolic impaction occurred, and the presence of flatulence with diarrhœa, together with the pathological evidence—viz., the rapid decomposition, the congestion of all organs, the absence of pelvic cellulitis, and the condition of the uterus,—lead me, notwithstanding the fact that in many respects the case ran a very unusual course, to think that some form of puerperal septicæmia was present. The puerperal state of the blood, the morbid condition of the aortic valve, slight though this was, and the unusual strain upon the heart from the high temperature and sudden change of position of the patient, may account for the formation, point, in the absence of pulmonary thrombosis, to the source, and explain the departure of the travelling clot or clots.

AT Exeter, on the 10th inst., the Mayor laid the foundation-stone of a new Asylum for Pauper Lunatics. The building will cost some £100,000.

DISLOCATION OF THE STERNAL END OF THE CLAVICLE, BACKWARDS AND UPWARDS.

BY J. HARRY POLAND,
CHIEF MEDICAL OFFICER, SANDHURST HOSPITAL, VICTORIA.

R. G——, aged twenty, was admitted to hospital on Feb. 22nd, 1880. While wrestling with another man, both fell, the patient being underneath. He came at once to the hospital. On admission, the patient complained of pain in the right shoulder and inability to use the right arm; slight difficulty in breathing, and great difficulty and pain in swallowing. He was unable to say in what position he fell. On examination the right shoulder was slightly lower than the left, and projected more forwards; the arm was extended and kept at an angle of about 40° to the body, this being the least painful position. The head was inclined and turned slightly to the left side. There was a well-marked depression at the right sterno-clavicular articulation, and the sternal end of the clavicle could be felt beyond this, and at about three-quarters of an inch higher level than the corresponding articulation, the trachea apparently being pushed to the left side. The line of the clavicle could be felt throughout, and also the vacant sternal articulation. The patient was seated in a chair and reduction effected by placing the knee in the hollow between the two scapulæ, taking firm hold of the upper part of the arm and shoulder, and bringing them backwards and a little upwards. The parts were retained in position by means of a large pad placed over the right scapula, and the right arm bandaged so as to keep it well backwards, the elbow a little upwards, and the forearm folded across the chest. There was some difficulty in keeping the parts in position, and the bandage had to be reapplied three or four times. The head of the clavicle did not completely resume its normal position, and at the end of four weeks, when the patient was discharged, a slight depression could be felt over the articulation. There was, however, not the slightest trace of any upward displacement. The patient has since resumed work, and experiences no inconvenience from the injury.

Beyond the comparative rarity of the lesion, the only point remarkable is the absence of dyspnœa, which in this case was almost complete. This seems to have been due to the head of the bone forcing the trachea to one side, instead of directly pressing upon it. Of all the authorities I have been able to consult I can only find one other case in which dysphagia was the prominent symptom and dyspnœa absent, or nearly so. The case referred to is that of Sir Astley Cooper, in which he removed about an inch of the sternal end of the clavicle to relieve the dysphagia, but in this case the cause of the luxation was spinal curvature. This case is given in both Fergusson's System of Practical Surgery and in Holmes' System of Surgery. Of the other cases quoted, Hamilton, in his treatise on Dislocations and Fractures, gives some thirteen cases, five of which were the result of direct violence, and the remainder by indirect violence; and from various other authors I have collected seven other cases, two of which were the result of direct and five of indirect violence, making a total of twenty cases, seven from direct and thirteen from indirect violence. In one case, Dr. Brown's, of Callington, the cause was a fall in wrestling; but there, as in the present case, it is doubtful whether there was direct or indirect violence, since, when wrestling, men are not likely to be able to say the exact position in which they fall. According to Dr. Brown's case it was indirect, but in the present one, if the man could be relied on as to the position, it was probably direct violence that caused the injury, the patient stating that he fell with his right shoulder against the kerb, while his opponent was immediately above him. In any case, however, this injury seems to be far more frequently the result of indirect violence. Further, it is generally accompanied by dyspnœa, rarely by dysphagia alone, and not unfrequently by both, the former, however, being the most urgent symptom. It is, according to all authorities, seldom completely reduced, and is not unlikely to give some trouble to retain the parts in position. In the majority of cases the displacement is backwards only, and in those in which it is backwards and upwards the upward displacement is

Digitized by Google

slight compared with the backward. The diagnosis is easily made, and the reduction and treatment similar to that employed in the foregoing case.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF TUBERCULAR PERITONITIS AND PLEURISY; CYSTITIS; DIPHTHERIA; NECROPSY; REMARKS.

(Under the care of Dr. F. ROBERTS.)

FOR the following interesting notes we are indebted to Mr. Thomas Wilson, M.B., B.S. Lond., late house-physician.

F. T——, aged fifteen, a "stripper" in a telegraph works, was admitted on Nov. 15th, 1883, complaining of pain in and swelling of the abdomen. At his work he had been exposed to draughts and damp, his diet had been deficient in meat, but his clothing had always been plentiful and warm. Until the present illness he had always enjoyed fairly good health, though he had never been robust. The family history was good. About Nov. 1st he experienced a chill, but did not feel unwell till two or three days after, when he became rather drowsy and apathetic. Two days later he complained of pain in the hypogastric and lumbar regions and of headache. Shortly afterwards his abdomen became distended and his appetite failed. The bowels were in a normal state. About this time the patient received a blow on the lower part of the abdomen, causing pain, which, however, soon passed away. About a week before admission he was, he stated, unable to pass urine for two or three days, and the quantity afterwards passed was diminished. On Nov. 9th the abdomen became painful and also more swollen. Since then the man had suffered much from thirst. During the fortnight previous to admission he had experienced much discomfort from external piles. There had been no constipation or diarrhœa.

On admission the patient was found to be a slightly-built, badly-nourished lad, with a sallow and anæmic complexion, and an anxious, fretful expression. He could lie without absolute discomfort in any position, but preferred lying on his right side, with his legs slightly flexed. Temperature 102° F. There was great thirst. Appetite fairly good; no nausea or vomiting. Bowels opened once or twice daily; stools semi-fluid, light in colour, consisting of curdy-yellowish material, with occasional light-green-coloured streaks. Lips dry and cracked; breath very offensive; tongue covered with thick, creamy fur, except at tip and edges, which were red with prominent papillæ. The abdomen was much distended, especially in the upper half; its walls were very tense, and not œdematous; the umbilicus protruded slightly; there was no marked bulging of the flanks. The lower margin of the thorax was somewhat everted. There was slight fulness of the superficial veins. The abdomen felt very tense, the resistance being greater in dependent parts. There was no marked tenderness on manipulation. There was dulness on percussion in the flanks, extending as far forwards as the anterior superior iliac spines when the patient was lying on his back. Each flank became resonant when the patient turned on the opposite side, the dulness then rising on the lower side. Distinct fluctuation was obtained between any two points in the area of dulness. The liver dulness reached as high as the fifth intercostal space in the right vertical nipple-line; the lower border could not be defined by palpation or percussion. The splenic dulness was not increased. Respiration 30, shallow, and thoracic. Slight cough with clear mucous expectoration. No abnormal pulmonary signs. Pulse full, regular, moderately compressible. Heart sounds weak, but otherwise normal. There was no pain, but some difficulty in micturition. Urine acid; it contained no sugar or albumen, but large deposit of amorphous urates on standing.

On Nov. 16th the patient complained of sharp, scalding pain in the abdomen, especially over the lower ribs. On the 17th the urine became alkaline, depositing a large sediment of phosphates. The bladder was very irritable. There was great thirst; no vomiting; slight diarrhœa, with light coloured stools; tongue thickly coated. The temperature varied from 101·4° to 103·2°. The urine continued alkaline till the 23rd, when it was again noted as being acid, and free from deposit and albumen. The abdomen was more tense, but less painful and tender. The thirst and diarrhœa continued. Temperature 101·2° to 103·4°, generally slightly higher in the evening. On the 26th the patient vomited twice. The diarrhœa and thirst continued, but to a less degree. The abdomen was more distended and tense, especially in the epigastric region. The man now began to suffer from troublesome cough and more difficult breathing. On the 28th the patient was stated to have been delirious during the night. There were signs of fluid in both pleuræ as high as the angles of the scapulæ. There was cough with expectoration of greenish glairy mucus, streaked with blood. The diarrhœa was worse. There had been no return of vomiting. Pulse 112, weak, irregular, and rather dicrotic. Temperature 101·6° to 103·6°.

On Dec. 3rd the patient remained in the same condition, except that the bowels were now rather confined. On the 7th the abdomen was distinctly larger and more tense; the signs of fluid at the base of the left lung were much less marked; the man slept better. On the 10th he vomited a little bitter yellowish fluid. On Dec. 14th the abdomen was aspirated, 212 ounces of clear yellowish serous fluid being withdrawn, a portion of which became solid on boiling. On the 17th the skin of the abdomen was hot and dry; there were still signs of a considerable quantity of fluid in the abdomen, and the signs at the bases of the lungs remained as before the tapping. The bowels were opened once daily, the motions being formed. There was catarrh of the nasal passages. On the 18th the urine contained a small quantity of albumen for the first time. On Dec. 19th the soft palate and fauces were found to be covered with thick greyish-white exudation, and the patient was isolated. His breathing was very laboured, on account of the obstruction in the throat and nose. The swelling of the abdomen was increasing. There was some œdema about the ankles. He slept fairly well. Temperature 100·6° to 102·8°; skin hot and dry. On the 20th there was more membrane about the throat; the lips and teeth were covered with sordes; the urine contained a large quantity of albumen. Temperature 101·2°; pulse 120, small and compressible. On the morning of the 21st the pulse was 148; the nasal passages and throat were covered with thick greyish-white exudation. The patient gradually sank, and died from asthenia in the evening.

Necropsy, sixteen hours after death.—The peritoneal cavity contained a large quantity of clear yellow serous fluid. The parietal layer of the peritoneum was from a quarter to a third of an inch in thickness, and adherent to the subjacent organs by a thick layer of reddish lymph. The intestines were firmly matted together; on separating them a large number of grey granulations were seen beneath the lymph. The liver and spleen were adherent to the surrounding parts by thick layers of lymph, beneath which the peritoneal coverings were found to be infiltrated with grey granulations. These organs were otherwise fairly healthy, as were also the heart, kidneys, and brain. The mucous membrane of the intestines showed no sign of ulceration or of tubercular deposit. The left pleural cavity contained ten ounces, and the right six ounces, of blood-stained fluid; no adhesions. Over the posterior aspect of the lower lobe of the left lung there was a fine coating of lymph. Over this surface and in the fissure numbers of grey granulations were scattered in the pleura. The right pleura was similarly affected. The lower lobes of both lungs were œdematous. No tubercles were observed in the substance of the lungs. There was an enlarged bronchial gland with caseous masses in its centre at the root of the right lung. Both tonsils, the soft palate, and the epiglottis were covered with a fawn-coloured, pultaceous, easily separable membrane. This extended down the pharynx as far as the cricoid cartilage, and was continued through the larynx and into the trachea for two inches. The glands about the angles of the jaw were enlarged.

Remarks.—This case is interesting from the localisation of tubercle in the pleura and peritoneum, no deposit being found in the substance of any of the organs. The diagnosis of the cause of the peritonitis on admission was somewhat obscure; the age of the patient, insufficient diet, and unhealthy occupation pointing to tubercle, while, on the other hand, difficulty in accepting this diagnosis was found in the

Digitized by Google

absence of tubercle from the family history as far as it could be ascertained, and in the absence of signs in the lungs. The parents were inclined to attach considerable importance to the history of a blow, but this did not seem warrantable. The finding of an enlarged caseous bronchial gland at the root of the right lung is of considerable interest in relation to the etiology of tubercle. That the gland was affected prior to the deposit of tubercle would appear likely from the latter not having undergone fibrous or caseous degeneration. The presence of nasal catarrh was noticed on December 17th, but the presence of albumen in the urine next day for the first time rendered it probable that the nasal affection was diphtheritic. Unfortunately, attention was not drawn to the throat till the 19th, on which date a considerable quantity of membrane was observed. The cause of diphtheria was obscure; no contagion could be traced; the drains connected with the ward in which the patient was placed were not, however, in an unsatisfactory condition. The special receptivity of tuberculous persons for diphtheria is mentioned by Dr. —— in Quain's Dictionary (p. 374).

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

CASE OF PACHYMENINGITIS; NECROPSY; REMARKS.

(Under the care of Dr. TOTHERICK.)

FOR the notes of this case we are indebted to Dr. E. A. Dingley, house-physician.

William H——, aged fifty-seven, a labourer, was admitted on April 27th, 1884. The patient's history was fairly good, but formerly he had indulged rather freely in alcohol. No history of syphilis could be obtained. About the end of March, when at his work, he fell down some steps into a cellar, the depth being about fifteen feet. He was slightly stunned by the fall, and had a deep cut on the left temple, which bled freely, but otherwise seemed none the worse for the accident. The next day he returned to his work and continued at it for four days, and then gave up, complaining of giddiness and of pain in the head, but still seemed in fairly good health. This continued with a slow increase of the symptoms till April 26th, when he left home for a walk, and did not return in the evening, but was found lying in a ditch, paralysed and partly conscious. He was taken to a house, and the next day brought to the hospital.

On admission the patient's temperature was 99°. He was conscious, but very heavy and dull. When spoken to loudly he replied rationally, but did not make any voluntary statement, and could not remember the circumstances of his attack. As regards his motor power, the left arm and leg were paralysed, and also the left facial nerve. The tongue deviated to the left when protruded. The other cranial nerves were normal, and there was no paralysis of the trunk muscles. Sensation was normal, both as to acuteness and localisation. The superficial reflexes were increased; the knee-jerk was very easily obtained in both limbs, and ankle clonus was very well marked on the left side and slightly on the right. The pupils were equal, and reacted to light and to accommodation. He passed his urine in the bed, but retained his fæces. The left limbs were rigid. His arteries were rigid and tortuous, and the pulse slow, full, and regular. The heart sounds were rather weak, but no murmur could be distinguished. Respiration was slow and rather laboured, but there were no abnormal physical signs in the chest. His tongue was clean; there was no vomiting, and the bowels were confined. The abdomen was retracted. Urine was abundant, of low specific gravity, and contained no albumen.

During the first week the patient was in the hospital he improved considerably, and could move his left arm and leg to a considerable extent. He also was able to take light diet. On May 4th he seemed more drowsy and apparently slept all day; on the 5th it was difficult to rouse him, and on the 6th he was in deep coma and could not be roused. His limbs were quite flaccid and motionless on both sides, the pulse was 60° and decidedly irregular, and he had Cheyne-Stokes breathing very well marked. On the 7th he was in much the same condition, except that the breathing was irregular and superficial; and on the 8th he died. As it was an inquest case, the post-mortem examination was delayed for four days.

Necropsy.—Rigor mortis passed off; no external wounds or bruises, except an old cut on the left side of the forehead. On removing the calvaria and opening the dura mater the right hemisphere appeared to be covered with blood; this extended all over the convexity of the brain nearly to its base, but was strictly limited to the right side, and did not extend along the falx cerebri. On careful examination this turned out to be a very thin and delicate membrane, translucent and of a yellowish-red colour. It was composed of two layers—one spreading over the pia mater and not dipping into the sulci; and the other and more important one adherent to the under-surface of the dura mater, from which, however, it could easily be stripped off. When removed, the membrane was found to contain in its substance numerous clots of blood, varying in size from a pin's head to a plum-stone. On close examination, many of the larger ones were found to consist of two parts—the one being more recent than the other, which was paler and harder; the clots were more numerous and larger in the vicinity of the vertex; there was no free blood or clots, except those in the new membrane; there was no sign of lymph or pus; the vessels of the pia mater were congested and distended, but not ruptured; the vessels at the base of the brain were healthy. The brain was cut into small slices and carefully examined, but no trace of hæmorrhage or softening could be found. There was no fracture of the skull; the spinal cord was normal; the aortic and mitral valves were thickened, and on one of the cusps of the former there was a small projection about the size of a pin's head. The lungs were very emphysematous and congested at the bases; the liver was of the "nutmeg" variety and the kidneys smaller than natural.

Remarks.—This is one of those cases which show the importance and value of a post-mortem in every instance, for if there had been no examination one could never have certainly diagnosed pachymeningitis. The chief points of interest in the case are the severe blow on the left side of the forehead, causing the formation in about seven weeks of the pachymeningeal membrane over the right hemisphere, this causing only slight giddiness, &c.; then came the first hæmorrhage into the membrane, causing the left hemiplegia and semi-unconscious condition in which the patient was found on April 26th. From this he recovered in great part, till a fresh series of hæmorrhages into the membrane on May 5th and 6th caused his death by pressure on the brain. During the whole time his temperature was not over 99°. The occurrence of well-marked Cheyne-Stokes breathing and the retraction of the abdomen are interesting points.

Sympathetic Neuro-retinitis.—Miners' Nystagmus.—Model Apparatus for demonstrating Operations on the Eye.—Congenital Defects.—Cataract Extraction for Lacrymal Obstruction or Catarrh.—Cystic Tumour of Iris.—Head Injury followed by temporary Blindness and Anosmia.

A MEETING of this Society was held on July 4th, Mr. Jonathan Hutchinson, F.R.S., President, in the chair.

Dr. BRAILEY showed a living specimen of Sympathetic Neuro-retinitis.—Mr. NETTLESHIP inquired of the precise order of events in this case.—Dr. BRAILEY said there were no symptoms of disease until March 6th, when the patient received a cut from a jug in the left eye right through the ciliary region. Aching in the right eye began two weeks later, and vision began to fail. One week later vision was $\frac{6}{60}$, the optic disc was slightly swollen, its margins blurred, vessels rather contracted, and some edged with faint white streaks for a short distance into the retina. The vessels near the yellow spot were rather larger and more numerous than usual, and also somewhat tortuous. Since then the vision has improved to $\frac{6}{24}$, but the optic disc has become flatter and more white. The left eye remained *in statu quo*, and no pain had been felt since the first week of the injury.—Mr. HUTCHINSON said that the lapse of only two weeks before the supervention of optic neuritis in the other eye was remarkable.—Mr. ADAMS FROST narrated a somewhat similar case.—Mr. NETTLESHIP asked whether the failure of sight preceded the ophthalmoscopic changes.—Dr. BRAILEY said

Digitized by Google

that when he first saw the case optic neuritis was present and vision had failed.

Mr. SIMEON SNELL read a paper on the Cause of Miners' Nystagmus, and stated that he had long held the opinion, as the result of clinical experience, that the cause of the disease was to be found in the peculiar manner in which the miner performed his work, whatever secondary influences and other surrounding circumstances might exert. He had seen no evidence to support the theory of central disease, and believed the poor illumination of the safety lamp, and other causes mentioned by writers, were insufficient to account for the affection. He described the various classes of men engaged in a coal pit, and the kind of work performed by them. The disease appeared to be confined to the coal getters. He had previously stated that, in his experience, men suffering from this affection had been engaged in work which necessitated their lying on their sides. Some of the coal getters were employed in this manner in what was termed "holing," the process of driving a cutting under the seam of coal, and the hole made might reach a yard or more underneath the coal. This was done to facilitate bringing down the coal by wedges. The hole made might be only eighteen inches to two feet high, and a man working in this would be cramped up and lying on his side. Further experience had completed the opinion expressed nine years ago, and though cases were constantly under observation, he believed they had all been engaged in the manner mentioned. He stated also that he had descended into a pit, and, as anticipated, found the men occupied in "holing" and working on their sides affected (four out of six examined), whilst other coal-getters and other workers in the pit appeared to be free from it. Other evidence in support of this view was adduced from the cases mentioned in Mr. Oglesby's paper (Transactions of the Ophthalmological Society, vol. i.) and also the opinion of Dransart (Annales d'Oculistiques, 1877) that all the sufferers had worked in shallow inclined bearings. Mr. C. S. Kilham had also, at Mr. Snell's request, examined in Durham over 500 colliers, and found not a single instance of nystagmus; in none of these pits were the men occupied in work compelling their lying on their sides. Dransart had held the disease to be due to fatigue induced in the elevators by the frequent upward gaze of the miners at work. Mr. Snell explained that, working in the manner mentioned, it followed that the eyes were frequently thrown into an oblique position upwards to the left or right—a position much more fatiguing than simply looking upwards. The muscles affected would thus be the superior rectus, the inferior oblique, left internal rectus, and right external rectus, if looking to the right, or substituting the right internal rectus and left external rectus if looking to the left. He considered the nystagmus arose under conditions recognised as "chronic fatigue" in other regions, and analogous to writers' cramp, &c. Recovery took place if the patients ceased their work in the pit in a variable time; it was quite possible that changing the manner of work would be quite sufficient. Strychnia and other remedies appeared to be useful adjuvants.—Mr. JONATHAN HUTCHINSON said that he believed Mr. Snell had come nearer to the position taken up by Mr. Oglesby than he seemed to think. With regard to causation, the miners in Cornwall did not work long hours, had good light, and adopted the sitting posture. Amongst these nystagmus was practically unknown. The analogous affection known as "writer's cramp" was most probably due to some fatigue of the nerve centre. Mr. Oglesby had pointed out that with some cases of miner's nystagmus a form of epilepsy was associated; and, further, some patients had been relieved by the use of bromide of potassium. Mr. PRIESTLEY SMITH said that he agreed in a great measure with Mr. Snell, but he would be inclined to lay more stress on some points on which Mr. Snell laid less. As to whether peripheral or central disturbance of function was the cause, he would say that the affection was invariably bilateral and symmetrical, although unequally so. He should look upon the affection as due to a perverted nutrition of the centres in the brain; he thought that this view was borne out by the fact that the nystagmus was rotatory in one case which he had seen. It ought to be remembered that stimuli received from the retina had a great deal to do with fixing the attention on any object. Most favourable conditions for malnutrition existed in the surroundings of the miners, which further made fixation of the eyes exceedingly difficult. Instances were given tending to show that the nerve centres lost their good vigorous action in the absence of well-formed retinal pictures. Such states of ill-health as anæmia, aided by the horizontal posture, and any condition of nervous exhaustion would favour the production of malnutrition of the centres.—Dr. BRAILEY considered that little doubt could be entertained that muscular fatigue rather than any defective nutrition of the nerve centres was the fault. If anyone looked up and to the left continuously, he would find that the eyes would become nystagmic.—Mr. NETTLESHIP asked how cases of unilateral nystagmus could be explained on the central theory where the eye was blind or vision defective.—Dr. STEPHEN MACKENZIE thought that we could not separate the fatigue of the muscles from that of the energising centre. He was of opinion that it was a central disease. In all muscular action there was a balance of antagonistic action, and a more careful adjustment would be required in those cases where the men worked on their sides, so that the balance of antagonism could be more easily disturbed and the muscles most in action would be found to fail first. The occurrence of nystagmus in cases of central nerve disease—e.g., disseminated sclerosis—favoured his view.—Mr. ADAMS FROST drew attention to the difference of practice which prevailed in different mines. Where the Davy lamp was not in vogue nystagmus was not found. The miners assign the lamp as the cause, but it was probable that the causes which led to the use of the lamp also developed the nystagmus.—Dr. BEEVOR expressed his belief in the central origin of nystagmus, as was certainly the case in disseminated sclerosis. Mr. PRIESTLEY SMITH explained unilateral nystagmus by supposing that one centre of the bilateral nucleus may be atrophied.—Mr. MCHARDY considered that the unnatural use and fatigue of the muscles used might lead to a condition of diminished conductivity of the nerves involved.—Mr. SIMEON SNELL, in reply, urged that although both eyes were affected yet it could not be denied that one eye was always worse than the other. As Mr. Hutchinson had explained, Oglesby's view more especially dealt with the notion that a congestion of the central apparatus was at work, and not that position was the essential factor.

Mr. J. F. STREATFEILD showed a Model Apparatus for demonstrating Operations on the Eye. After commenting on the difficulty of demonstrating ophthalmic operations to a large class owing to small dimensions of the organ, and the impossibility of all the members of a class of students catching even a glimpse of the manipulations, he explained the construction and uses of a large model made for him by Hawksley, of Oxford-street. The model was made on a scale exactly ten times that of the actual eye, and the models of the eye instruments were on the same scale, excepting the handles of the instruments, which had been altered and shortened. The apparatus allowed of a fair amount of rotation in every direction, and the front hemisphere of the eye could be fixed in any desired position. The sclerotic and the eyelids were constructed of white felt. The cornea was made of stout glass of the right curvature. The iris was imitated in thin sheet indiarubber, with a round hole for the pupil. The cataractous lens was made of xylonite. The internal and external rectus muscles of the eye were represented by pieces of linen bandage. With this apparatus could be represented the *modus operandi* of the peripheral section of the cornea, of iridectomy, of extraction of cataract, and of squint operations. The anterior chamber could only be entered for iridectomy, cataract extraction, &c., in the usual place, at the sclerotico-corneal junction. Here, at any part of the upper half-circumference, the knife, forceps, pricker, or curette could be entered between the felt sclerotic and the glass cornea, which gave way for their admission, and resumed its natural position when the instrument was withdrawn. The sheet indiarubber of which this imitation iris was made could be seized with the (model) iris forceps at any part, drawn out of the eye more or less, and so much cut off as might be desired in the demonstration. Mr. Streatfeild illustrated his remarks by performing a cataract extraction on the model.

Mr. J. F. STREATFEILD read a paper on a Preliminary Precaution to be taken in cases of Cataract Extraction when there is, or has been, any lacrymal obstruction or catarrh. The operation, in such cases, involved an almost certain failure of the worst kind; and as the cause of failure in these cases had been overlooked or misunderstood, this catastrophe seemed to have been almost as inevitable as it was complete. When suppuration followed purulent infiltration of the corneal wound, when it occurred as the direct and immediate consequence of the extraction operation, it was the common, almost

Digitized by Google

invariable, beginning of the suppuration of the whole eye. These cases were of course not common, because the absolute loss of an eye after cataract extraction operation, from any cause, was a rare event; but absolute loss of vision was, as a rule, the result of suppuration. He had had two such cases within the past year,—one in private practice, and the other in Moorfields. The cause of this suppuration after cataract extraction, he was inclined to think, was generally some lacrymal obstruction, and secretion of purulent matter from the outlets of the tears in connexion with the eye operated on. No surgeon would think of operating for extraction when there was any lacrymal catarrh, or at least when there was any purulent regurgitation from the lacrymal sac, or indeed, any pus of any kind, or from any part of the mucous surfaces within the palpebral aperture; but the state of the lacrymal mucous membrane was difficult to investigate, and it was liable to be considered to be in a healthy state when it was not so. A purulent discharge from either mucous tract, but especially from the lacrymal mucous membrane, was likely to recur at any time, especially if an operation on the eye had been done. An inconspicuous quantity of pus would be sufficient to infect the corneal section. In the case of J. L——, a thin and healthy countryman, aged sixty-eight, admitted into Moorfields Hospital on July 4th, 1883, with mature cataracts, both the lower lacrymal puncta were somewhat everted, and, consequently, there was an overflow of the tears in either eye. The lower canaliculi were slit. Pus was found in the lacrymal sac on either side. After this the nasal ducts were probed every day, or nearly every day, for ten days, and the cure seemed to be complete. On July 16th the left cataract was extracted. On the day after the extraction a purulent infiltration of the wound at the upper part of the cornea had begun, and spread rapidly thence; the eye was very soon lost for all practical purposes, and on July 23rd it was excised. The patient left the hospital on August 2nd. On November 24th he was readmitted; there was some lacrymation of the right eye, but no evidence of any pus in the discharge from the sac at this time. The lower canaliculus, which had been slit, was patent. The eye was in all respects healthy with the exception of the opaque lens. Now, this was a very unsatisfactory state; there was no difficulty in passing the large probes and there was no pus to be seen in the discharge, but recovery was not complete. Mr. Streatfeild resuscitated the old operation for the total obliteration of the lacrymal sac, the canaliculi, and all the lacrymal mucous surface, which used occasionally to be performed twenty years ago for chronic obstinate discharge from and distension of the lacrymal sac, from obstruction of the nasal duct. On December 10th the upper canaliculus of the right eye was slit from the puncture to the lacrymal sac; when the bleeding had stopped the eyelids were held widely apart, the eye itself being covered and protected, and the pointed end of Paquelin's thermo-cautery was passed rapidly in the direction of first one and then the other canaliculus, along them, and quite into the sac. He then made a skin incision over the lacrymal sac, rather longer than the whole of its extent, downwards and a little outwards, between the root of the nose and the lower eyelid; this was then continued into the mucous cavity itself; and, when the bleeding was arrested, the two edges of the deep incision were held widely apart, and the broader end of the cautery was very freely and repeatedly applied to all parts of the exposed mucous surface, from the top to the bottom of the sac. The cavity was stuffed with carbolic oiled lint. On January 1st the wound had healed, and the sac and the canaliculi were apparently obliterated. There was a slight lacrymation, but there was no pus or any muco-purulent matter in the eye. On April 23rd he was again admitted. There was then a depressed scar in the place of the lacrymal sac, and a small hole leading down that direction; there was also an indication of a part of the lower canaliculus. The following day the cautery was again applied to the fistulous orifice and to the remains of the lower canaliculus, and on May 8th for a third time. On May 20th there seemed to be no trace of the canaliculi remaining, and no indication left of a lacrymal sac. There was now no discharge upon the conjunctival surface at any time; the flow of tears was not much, and it was no longer troublesome. On June 2nd the cataract of the right eye was extracted. The eyelids were washed with a one in forty solution of carbolic acid before the operation, and boracic acid ointment, ten grains to one ounce of vaseline, was smeared on the dressing. A weak solution of boracic acid was used subsequently every day to bathe the eye, and the same ointment was reapplied with after-dressings. Slight ciliary congestion with photophobia occurred about a fortnight after the operation, but the patient made a good recovery. The objections to the obliteration of the lacrymal sac were not practically very strong; and, in the cases in which he advocated a revival of this obsolete practice, it seemed to be absolutely necessary in order to succeed in operating for cataract subsequently.

Mr. SIMEON SNELL related the following cases of Imperfect Development. 1. Congenital cysts in the lower eyelids, with (apparent) anophthalmos. The patient was an infant of a few weeks. In the left lower eyelid a large cyst, with bluish tint, was situated; it extended deeply into the orbit. On being tapped the fluid escaping was straw-coloured, and corresponded, on analysis, to that examined from similar cases recorded as "congenital cysts with anophthalmos." Subsequently the cyst wall was partially excised, and it was thought a rudimentary globe was detected at the back of the orbit. In the right lower eyelid, at first, there seemed to be a very small cyst; it was not tapped, and a year later it was hardly apparent. Here also a resistance, particularly at the later period, was detected in the orbit, and was thought to indicate the presence of a rudimentary globe. Both orbits were normally developed. 2. Congenital cyst in lower eyelid with micro-ophthalmos; the infant was under the care of Mr. W. M. Jones of Wath. The cyst filled the orbit. After dissecting it out, a micro-ophthalmic eye came into view. The cornea was well formed, there was a coloboma at the lower part of the iris, and the eye was possessed apparently of some vision. An ophthalmoscopic examination was made, and, as far as could be made out, the child was almost moribund with tubercular peritonitis. The coloboma extended into the choroid, but did not reach to the optic disc. The cyst in the eyelid presented a bluish tint; the fluid was straw-coloured. Mr. Snell quoted the recorded cases, and remarked on the various causes assigned for the origin of these cysts by Talko, Manz, Van Duyse, and others. The theory advocated by Van Duyse, that they arose from the encysting of a staphylomatous coloboma, was held to correspond with their association with micro-ophthalmic or rudimentary globes. 3. A case of absence of eyeball on one side. 4. Micro-ophthalmos of the left eye, with coloboma of the optic nerve-sheath, and coloboma of the choroid in the right eye. The fundus in the left eye displayed the rare condition described as coloboma of the optic nerve-sheath; the coloboma was six or eight times the size of the optic nerve, perhaps being the largest recorded on the left side. V = fingers, possibly more; on the right, V = $\frac{1}{60}$. Between the optic disc and the periphery below, a pearly white patch was situated; the edges were well-marked and pigmented; otherwise the fundus was normal. This was considered to be congenital, and to be due to arrest of development (coloboma of the choroid). In neither eye was there a cleft of the iris, nor any deformity beyond those named. Nystagmus, affecting both eyes, was present. 5. Remains of hyaloid artery. The attachment to a vessel in the centre of the optic disc was clearly made out; at this point it was a little more funnel-shaped. Anteriorly, it was attached to the posterior lens capsule, where it occasioned a striated opacity. V = fingers at one foot. The eyes were myopic. 6. Coloboma of upper eyelid, situated at the junction of the inner with the middle third. There was also a lipoma of the conjunctiva.

Owing to the lateness of the hour, the two papers of which we are able to give the following abstracts were taken as read.

Mr. W. J. CANT, of Lincoln, related a case of Cystic Tumour of the Iris. The patient was a man, aged forty, suffering from loss of vision of the right eye, which prevented him from following his occupation; when a boy it had been injured by a piece of steel, but apparently it completely recovered. About three years ago his eye again began to trouble him, and he noticed soon after something growing over the sight which gradually increased. On examination, a cystic tumour was seen almost filling the pupil, growing from the iris at the upper segment. V=$\frac{1}{12}$, and he read Jaeger 16 with difficulty. A fundus reflex could be obtained through the tumour. The tension of the eyeball was increased (Tn+1 or 2). His left eye was almost useless from opacity of the cornea. The tumour, with a piece of iris, was removed through an upper section, and afterwards an iridectomy downwards was made. The eye completely recovered with good vision, V=$\frac{1}{1}$, and Jaeger 2.

Digitized by Google

Mr. CANT also contributed a paper on a case of Injury of Head, followed by temporary Blindness and Anosmia. The patient, a potman, threw himself out of a window a height of 40 ft., and was taken up in an unconscious state. He regained partial consciousness, and then became violently delirious. After the swelling of the eyelids had passed off, he was found to be absolutely blind, and ophthalmoscopic examination revealed engorged optic discs. Loss of smell was also noticed at this time. In a few days the sight improved, and at the end of six weeks was quite restored. The anosmia, however, remained. The probable cause of these losses of sensory activity was hæmorrhage in the middle and anterior fossæ.

Mr. SIMEON SNELL showed a section under the microscope of a specimen of Bony Tumour of the Conjunctiva. It was removed from the right eye of a girl aged thirteen, and had probably existed since birth, but had caused no inconvenience until shortly before she came under observation.

Dr. WALTER EDMUNDS exhibited an ophthalmoscopic drawing from a case of Cerebral Tumour presenting appearances like those of albuminuric retinitis. There was well-marked double optic neuritis with hæmorrhages round the disc, there were also bright radiating lines at the yellow spot. The retinal veins were not tortuous.

Mr. LANG showed a child with a growth on the Iris of a possibly Tubercular nature. The eye had been noticed to be a little bloodshot about the middle of May. When first seen a month ago there were several growths on the lower part of the iris, and the cornea was hazy, the growths had since been steadily increasing in size, and there was pus in the anterior chamber.

Mr. A. CRITCHETT exhibited a patient with Conical Cornea on whom he had operated. Also, with Mr. TYLER, he exhibited a case of Squint cured by operation, and a leucoma of the cornea treated by tattooing, and the formation of an artificial pupil.

Mr. W. ADAMS FROST showed two cases of Double Optic Neuritis in Children. In the one case, which was a girl aged ten, the failure of vision had been preceded for several months by very severe headaches, accompanied by vomiting, and these still persisted. There was slight paresis of the left external rectus, but no other paralytic affection. The knee reflex was normal. The patient was a very healthy looking and intelligent child. There was no history of any personal illness or family tendency. The other was a girl aged seven. When first seen on May 1st, vision was said to have been failing a week. There was well-marked papillitis in both eyes. No history of headache or illness could be obtained at the time. A few weeks later the child was attacked with severe occipital pain and vomiting, and the headaches without vomiting have recurred frequently since. There seemed to be no paralysis of any ocular muscles. The left eye has improved slightly under small doses of mercury.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Medical Section held on April 18th, Dr. J. W. MOORE read an abstract of Surgeon-Major GORE'S paper on the Etiology of Climatic Fevers in India, which was before the section *in extenso* at the previous meeting, when, owing to the lateness of the hour, the discussion was adjourned. Surgeon-Major Gore showed that the common climatic fevers of the Kumaon Hill Ranges of N.W. Bengal presented themselves under two very distinct forms—namely, as intermittents and remittents. He disputed the doctrine held by some that remittent fevers were not to be met with in India as distinct from enteric fevers, and quoted briefly a description of the severe epidemic of malarial fever which prevailed in the neighbouring N.W. Provinces in 1879, which differed in no respect from that met with in many parts of Lower Bengal. Having alluded to the aqua-malarial fevers of the mountain regions of North America, as described by Waggoner and Smart, he referred to the observations of Macnamara and Walker on the presence of malarial fevers in the hills in India, and to the great varieties in the degree and severity of the types of malarial fever, which often obscured the diagnosis between malarial and enteric fevers. He showed how malarial fevers varied in intensity and duration according to the dose of the poison, exposure to intense heat, individual peculiarities of constitution, different altitudes, the causes of scurvy or acquired anæmia from a previous residence in the plains, giving examples from the records of the 30th Regiment. At the same time he pointed out how the malarial fever might ascend; in how many different ways it might be taken into the system; how the quinine test might be vitiated by a variety of circumstances, and what therapeutical combinations were necessary to render it effective, alluding to those congestive remittents caused by an excessive dose of the poison on the nervous system or blood, so altered from the natural standard as not to be amenable to any therapeutic combination which might be administered to avert a fatal issue.

Dr. J. P. DOYLE read a paper on a case presenting some symptoms of Disease of the Bladder. A gentleman, aged sixty-eight, came under his care in May last for irritability of the bladder and pain along the urethra, especially about an inch from the orifice. He consulted a London specialist, who from the symptoms expected to have found a calculus, but afterwards diagnosed enlargement with hardness of the right bone of the prostate, which he said by pressure on the nerves produced the pain, numbness, and lameness in the right lower extremity from which the patient suffered. He also informed him that he would not be free from the pain during his life. On January 18th inflammatory symptoms with great increase of pain set in. The slightest touch or movement produced increase of pain with contraction of the muscles of the thigh, which in a few days became very tense and swollen, and later on some stercoraceous vomiting ensued along with great tympanitic distension of the abdomen. The patient obtained great relief from puncturing the abdomen with the needle of a veterinarian's hypodermic syringe in the position of the ascending colon, which allowed the escape of a large quantity of very offensive gas. On post-mortem examination no calculus was found, and the bladder and prostate were normal. The veru montanum appeared enlarged; the cæcum, ascending colon, and vermiform appendix were found inflamed. The former were distended, and contained dark-coloured matter like moist charcoal, and the latter was filled with a hard mass, which on fracture looked like charcoal.—Dr. MORE MADDEN considered that all the symptoms pointed to disease of the bladder, including displacement of the cæcum, which gave rise to an amount of trouble sometimes under-estimated.

Dr. J. MAGEE FINNY read a paper illustrating the Identity of Progressive Muscular Atrophy and Progressive Bulbar Paralysis. The subjects of this communication were men of the labouring class, both from the country—one aged fifty, the other thirty-nine—who came under his care in the spring of 1882. The duration of the disease was seven and nine months respectively. In both disease began, without any discoverable predisposing or exciting cause, in the tongue, by impairment of speech and difficulty of deglutition, and after five or six months evidences of progressive muscular atrophy were perceived, although it was very probable that its occurrence was considerably earlier. The bulbar symptoms were extremely well-marked in each, though one differed from the other by the amount of glossal atrophy and the involvement of the lips. Fibrillary movements were noticed in the tongue of both, and in the lips of one. The constant dribbling of saliva, the difficulty of pressing the lips to blow smoke or spit, the difficulty of carrying the particles of food to the back of the mouth, were all well-marked, while speech was reduced to "aye" and "no" in one patient and to a few monosyllables in the other. In both the dentals and labial letters were impossible, and in one suffocative attacks from the food entering the larynx were frequently imminent. The amyotrophic changes were well marked in the neck and upper extremities of one and of both arms and legs in the other. Fibrillary movements were most distinctly seen in all the paralysed muscles. Sensation and tendon reflexes were unimpaired, and there was no paralysis of the bladder or rectum. In one treatment by barium chloride and frequent galvanism and faradaism seemed to arrest the progressive muscular atrophy, and even to restore to the deltoids the power they had lost, while the bulbar symptoms remained unaltered, though not increased. The other case was rapidly wasting, and the bulbar symptoms were worse. Both cases left the hospital, and their future progress was unknown.—Dr. C. J. NIXON observed that in bulbar paralysis there was always to be found a constant lesion in the motor roots of the nerves and the motor ganglia and the medulla. In all the post-mortem examinations there had been found constant trophic change in the motor roots of the nerves, whereas in nineteen recorded cases of progressive muscular atrophy no change whatever was found in the motor roots. Another pecu-

Digitized by Google

liarity was that the first sign was the atrophic condition of the muscles, while there were some cases recorded where, with distinct bulbar paralysis, there was no atrophy of the muscles at all. The absence of atrophy of the muscles could be explained by assuming the disease to be confined to the motor cells in the anterior grey horns, while the trophic cells in the neighbourhood had escaped the disease.—Dr. FINNY, in reply, acknowledged that Dr. Nixon had touched more points than he had dealt with in his communication; but he thought it was hardly time yet to come to any positive conclusion in comparing the two diseases, the number of observations on progressive muscular atrophy being much larger than that on bulbar paralysis.

Mr. STORY read a paper on Atrophy of the Nerves, and Paralysis of the First and Fifth, from probable tumour in the brain, the discussion of which was postponed to the next meeting.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting of this Society on June 6th, Mr. ROPER related a case of Cerebral Hæmorrhage simulating Opium Poisoning. Mrs. W——, aged sixty, had for many years suffered from renal stricture, for the relief of which she had been accustomed daily to use laudanum by enemata, using about sixteen ounces during the fortnight. About six o'clock P.M. on Thursday, Feb. 28th, she complained of feeling ill, different from anything she had ever before experienced, with pain at the back of her head and giddiness. She appears to have retched, although she did not actually vomit. She made several ineffectual attempts to swallow tea. Mr. Roper saw her about twenty minutes after nine, when she was in a state of profound coma. Upon inquiry he was informed that she had been unconscious since about eight o'clock. The limbs were flaccid, the eyelids closed, and the mouth open. The breathing was infrequent and noisy; the pulse full, forcible, and between 70 and 80 a minute. The carotids pulsated visibly. The pupils were minutely contracted, and sensibility was in abeyance. Towards the end the respirations became still less frequent, the pulse intermittent, and finally very feeble, but continuing to beat for two minutes after respiration had ceased. She died about ten o'clock. The post-mortem examination was made at a quarter to five on the following day. Rigor mortis had set in. The brain was removed and the membranes found much congested, and there was an area of great congestion upon the surface of the brain in the position of the left parietal eminence. There was a clot of the size of a large walnut occupying the centre of the right cerebellum. Mr. Roper brought this case before the Society, as the symptoms bore so close a resemblance to those which occur in opium-poisoning, and the case was therefore interesting from a medico-legal point of view, and as showing that it is not wise to place too much reliance on circumstantial evidence. This case differed from one which came under his notice two years ago, in which he found a small clot in the pons Varolii, in that consciousness was much longer retained, and the pulse remained full, regular, and firm till nearly the end; whilst in the other case, profound coma occurred almost immediately, and the pulse was extremely feeble and rapid.

Mr. CARVER alluded to the Treatment of Nævus with Ethylate of Sodium. He had tried it very successfully in several cases. It was easy of application and gave little pain. It should not be applied too freely or sloughing would ensue, but just enough to discolour the skin; then in about ten days the crust should be separated. After repeated applications, the blood is coagulated and a puckered mark remains. This after a time disappears, and there should be little or no scar left.

Mr. WHERRY showed a specimen of Fracture of First Rib, with Pressure on Subclavian Artery, which was taken from a patient who fell from a brake-van of a ballast train; the wheels crushed his legs so that both had to be amputated. Fever and delirium followed, the flaps partly sloughed, and the patient died three days after admission to the hospital. During life his breathing was quick and shallow. His chest was carefully examined, but no fracture of the rib could be discovered. There was a slight bruising about the left clavicle, and a musical systolic bruit heard just below the middle of that bone. There was dulness on percussion in this region. The radial pulse was alike at both wrists. After death the first rib on the left side was found to be fractured, the line of fracture running very obliquely from the tuberosity behind to the tuberosity in front. The subclavian artery was pressed upon by a displaced portion, and a great quantity of blood was extravasated about the vessels and fractured rib. The clavicle was not broken, nor were any of the other ribs. The left chest was full of bloody fluid, and the lung collapsed and consolidated.

Dr. BRADBURY showed portions of the Small and Large Intestines removed from a man who had died of Typhoid Fever, and afterwards read the notes of a patient, aged twenty-six, a plumber, under his care in the hospital suffering from Bright's Disease. In addition to his other symptoms, he had frequent attacks of colic and passed blood by the bowel. He was very ill when admitted on January 1st, suffering from dyspnœa and great debility, the urine containing much albumen. On the 13th he passed a quantity of blood in the night, followed by severe abdominal pain. On February 5th he suffered from severe pain over the heart, and after great distress died suddenly. Post-mortem: The kidneys were enlarged and firm, the capsules slightly adherent. The left pleura contained much fluid, and the heart was dilated and hypertrophied. The intestines were congested in many places. In the lower half of the small bowel were numerous patches of submucous hæmorrhage. In the upper part of the ileum were three small ulcers close together, the largest about half an inch long by one-eighth of an inch broad, superficial, the edges ragged but not undermined. The submucous tissue around was deeply stained with blood, and the ulcer appeared to have its origin in a hæmorrhage similar to that found elsewhere. Dr. Bradbury said that ulceration of the intestines was rare in Bright's disease. He thought it probable that the hæmorrhage into the submucous tissue was the cause of the ulceration, there being great tendency to hæmorrhage in the disease. He referred to cases recorded by Dr. Dickinson, in all of which the patients were under twenty-one, exceptionally young for granular kidney. His patient was only twenty-six.

Dr. HUMPHRY showed the Head and Neck of the Femur from an old woman which had been sent to him to prove that, as was usually accepted, the angle of junction of the neck of the thigh bone with the shaft was smaller in aged persons than in the adult. He believed this to be quite an erroneous notion, and indeed this specimen did not show it to be the case. What had occurred in this instance was that there had been disease and absorption of the upper part of the head, while new bone had been deposited on the under surface, so causing the appearance of alteration of the angle. Dr. Humphry thought it probable that the angle varied to a slight extent in different persons, but he could not allow that any change of this kind occurred from old age. It would be quite unique, for he was not aware of any such alteration of form occurring in any other part of the skeleton from this cause. He had in his possession the femur of an old woman aged 103, and the angle was as open as in the adult.

Reviews and Notices of Books.

An Introduction to Pathology and Morbid Anatomy. By T. HENRY GREEN, M.D., Physician to Charing-cross Hospital, &c. Sixth Edition. London: H. Renshaw. 1884.—The issue of the sixth edition of this work indicates its deservedly sustained popularity and value. It is not many years since the first edition appeared as "a boon and a blessing" to those who, then but tyros, are now representatives of pathological science in England. Fifteen years ago there were scarcely half a dozen serious students of pathology and morbid anatomy in England; there was certainly no distinct school. Now the votaries to these studies may be counted by hundreds, and the work done by many of them will bear comparison, as regards its thoroughness, ingenuity, or utility, with that of the best continental investigators. Dr. Green's book was a pioneer of the new movement, and it has done much from time to time to consolidate this enviable progress. It will therefore be a double pleasure to those who have not forgotten their early debts to find that the demand for Dr. Green's manual continues as great as ever, and that the author's ardour remains unabated.

Digitized by Google

The new edition has been carefully revised and brought up to the level of contemporary knowledge. Dr. Green acknowledges with satisfaction the co-operation of Mr. Stanley Boyd in the preparation of this edition. This gentleman has contributed the general introductory chapter and the chapters on Tumours, Degeneration, Septicæmia, Pyæmia, and Vegetable Parasites, including Bacilli. Every one of these articles is excellent. Though Dr. Green's manual has now two or three formidable competitors, we may confidently recommend it to the medical student and practitioner as altogether the best in our language.

The Extra Pharmacopœia of Unofficial Drugs, &c. By WILLIAM MARTINDALE, F.C.S., and W. WYNN WESTCOTT, M.B. Lond. Third Edition. London: H. K. Lewis. 1884.—The rapidity with which this excellent little work has passed through two editions testifies to its utility, as well as to the really remarkable attention that is given to pharmacy in the present day. Nor need the near approach of a new edition of the British Pharmacopœia at all interfere with the domain covered by Mr. Martindale's book, for it is safe to say that but a very small proportion of the drugs and preparations here described will as yet find a place in the official list. The compilers of the British Pharmacopœia are likely to err on the side of caution and conservatism, and will hesitate to include many useful remedies on the score of their novelty. Therefore we think that an extra pharmacopœia will always be of use, and if, as seems likely, the present work continues on its successful career, practitioners will be enabled to estimate at their true value many a novelty which might otherwise be neglected. Doubtless several of these new remedies enjoy but an ephemeral period of favour, but besides these there are many that will endure and will replace older and less efficient drugs. To enumerate the whole list would be to reproduce the index of the volume before us; but a selection of the following from its pages shows how various are these new remedies, which have gained considerable acceptance:—Abrus (jequirity), boroglyceride, bromide and iodide of ethyl, caffeine, chinoline and kairin, convallaria, homatropine, duboisin, emetine, erythrophlæum (casca bark), eucalyptol, hamamelis, hydrastin, iodoform, iridin, menthol, muscarine, not to mention the widely known salicine compounds and special preparations of drugs of old-established use. A great merit of this book is its conciseness, and the addition to the description of each drug of recorded experience of its effects. The index, which comprises a detailed "therapeutical" as well as a "posological" part, is also a feature; and it may be said of the book, with more truth than the phrase often conveys, that it should be the constant companion of every practitioner.

A Synopsis of the Bacteria and Yeast Fungi. By W. B. GROVE, B.A. London: Chatto and Windus. 1884.—This synopsis of the bacteria and yeast fungi and allied species (hyphomycetes and saccharomycetes) has been drawn up by the hon. librarian of the Birmingham Natural History and Microscopical Society. The aim of the little work is almost purely morphological. The first two chapters are translated, with additions (the more important of which are indicated), from Dr. G. Winter's edition of "Die Pilze" in Rabenhorst's "Kryptogamen-Flora." The book must be regarded as of much value as a work of reference, for it is decidedly laconic and elaborate.

Homburg vor der Höhe, a Health Resort. By H. S. C. WISE, M.D. Pp. 63. Homburg vor der Höhe: Steinmetz. 1884.—This little work contains a good deal of miscellaneous information respecting Homburg. After a brief historical notice of the spa from the beginning of the seventeenth century to the present time, the author gives an account of its climate as a health resort, and of the situation and composition of its mineral springs, which are of two kinds, chalybeate and saline. After some observations on the principal components of the spring, he enumerates briefly the diseases in which he thinks they may be used with advantage, and those in which they are contra-indicated. The latter are diseases of the bronchi and lungs, especially tubercular; diseases of the heart and its vessels, dropsical affections, softening of the brain, and acute inflammatory processes. The Kur establishments are described, and the dietary to be observed by the patients is detailed. The latter part of the work is devoted to an account of Homburg and its neighbourhood, with the excursions which may be made by visitors, and the amusements provided for them during the season. The book has been translated from the German by some one evidently not used to such work, and might easily be improved in its style, but it contains information which may be useful to those who are desirous of sending patients abroad to take a course of mineral waters. We are disposed to think that Dr. Heyd considers the waters applicable to too extended a class of cases, but he furnishes information which may enable physicians to decide whether they are likely to prove useful to the patients under their care.

Wiesen as a Health Resort in Early Phthisis. By A. T. WISE, M.D. London: Baillière. 1883.—This book has been written to bring to notice a new Alpine health resort. Wiesen is situated about eleven miles from and about 334 ft. lower than Davos. The mean temperature is said to be two or three degrees higher, and the winter to be shorter than at Davos. It lacks, however, many of the comforts of the latter, and is defective in some of the most important sanitary arrangements. "Promises are made that these defects will be remedied;" but we think it would have been judicious to postpone the publication of this book till these promises had been fulfilled. There are a number of meteorological tables relating to the period from Nov. 1882 to March 20th, 1883, but as we are informed in the preface that they "were made in a winter unprecedented in ten years," we fail to see how they can be useful. There is also a table giving the ages at death of the inhabitants since 1834, with a view to show how many deaths occurred at advanced periods of life, but as there is no information given of the numbers living at each age during the period, it is absolutely of no value, and may possibly be misleading. We do not think the remarks on clothing, diet, exercise, &c., add anything to the existing knowledge on these subjects.

The J.E.M. Guide to Switzerland. The Alps, and how to see them. Edited by J. E. MUDDOCH. Pp. 416. London: Wyman and Sons, 1884.—*The J.E.M. Guide to Davos Platz.* Edited by J. E. MUDDOCH. With Analytical Notes on the Food, Air, Water, and Climate. By PHILIP HOLLAND. Third Edition. Pp. 135. London: Wyman and Sons, 1884.—The first of these works is the fourth edition of a very good practical guide to Switzerland. It appears to contain the information which a tourist requires without being overladen with unnecessary details, and is of a portable and convenient size. The hints to travellers and the general information prefixed to the guide are judicious, and will amply repay the careful study of anyone intending to visit Switzerland. We have no hesitation in recommending it as a valuable guide book; it has also the advantage of a copious index.—The Guide to Davos Platz by the same editor gives a very good description of the place, its climate, accommodation, and amusements. In addition to all the necessary information respecting the routes by which it may be reached, there are two interesting papers by the editor on Alpine Climbing in the Winter. Written from a non-professional point of view, but with an evident appreciation of the importance of good sanitary surroundings, this little work appears to us to afford all the information required to enable the members of the profession

Digitized by Google

to judge of the value of Davos Platz as a health resort and of the precautions which it is necessary or advisable to impress upon patients sent there in the hope of arresting the progress of pulmonary disease.

The Riviera, or the Coast from Marseilles to Leghorn, including Carrara, Lucca, Pisa, Pistoja, and Florence. Illustrated with Eight Maps and Six Plates. By C. B. BLACK. 8vo, pp. 284. Edinburgh: A. and C. Black. 1884.—This is a very good guide book to the stations of the Riviera from Marseilles to Leghorn. It does not treat of them from a medical point of view, but affords all the information necessary for travellers generally, the means of locomotion, the hotels and boarding-houses, the excursions which may be taken from each of them, and the places of interest which may be visited. The maps and plans have been carefully prepared, and the volume is altogether worthy of the reputation of the publishers. It has the great advantage of containing a large amount of really useful information without being either tiresome or too large to be conveniently used as a handbook.

Health Exhibition Handbooks. Water and Water Supplies; and Unfermented Beverages. By JOHN ATTFIELD, Ph.D., F.R.S.—*Food and Cookery for Infants and Invalids.* By C. JANE WOOD; with an Introduction by W. B. CHEADLE, M.D.—*On the Principles of Cooking.* By SEPT. BERDMORE.—*Healthy Schools.* By CHARLES E. PAGET.—*Ambulance Organisation, Equipment, and Transport.* By Surgeon-Major G. J. H. EVATT, M.D.—*Fires and Fire Brigades.* By Captain EYRE M. SHAW, C.B.—These handbooks, issued by the Executive Council of the Health Exhibition, treat of the subjects indicated by their respective titles in a lucid and popular manner. They are not written for specialists, but for the information and enlightenment of the general public, an object which they are well calculated to attain.

Birmingham Medical Review. July, 1884.—The original communications of this number are:—The Surgery of the Kidney, by Lawson Tait, F.R.C.S.; Random Recollections of Eighteen Years' Experience of a Parish Medical Officer, by Jabez Jackson, M.R.C.P.; Cerebellar Disease, with Crossed Paralysis, by C. U. Suckling, M.D.

British Medico-Chirurgical Journal. June, 1884.—The current number of this quarterly journal contains an excellent article on Chorea by Dr. Long Fox. Ingrowing Toenail is treated of by Mr. Greig Smith, and Ligature of Main Arteries by Mr. Paul Bush. A case of Tumour (Columnar Papilloma) in the Fourth Ventricle of the Brain, with Hydrocephalus, is reported by Mr. J. Taylor.

The Journal of Mental Science. July, 1884.—Professor Herzen continues his dissertation on the Physical Conditions of Consciousness; Dr. J. A. Campbell discusses the question of "Unlocked Doors" in Asylums; Dr. Chapman institutes an inquiry into the value to be attached to the different Recovery-rates of different Asylums as Tests of Efficiency; Dr. Newington treats of Unverified Prognosis; Dr. Fox writes on Exaltation in Chronic Alcoholism. Interesting cases of Cerebellar Hæmorrhage are recorded by Dr. James Shaw; Mr. Bevan Lewis gives an illustrated account of an example of Post-Hemiplegic Hemichorea associated with Insanity; an illustrated case of General Paralysis with Pachymeningitis is described by Dr. Savage; and Dr. McDowall reports cases of Congenital Mental Defect with Delusions of Suspicion in Twins (with portraits).

The American Journal of Neurology and Psychiatry. May, 1884.—Our neurological brethren in America manage to keep pace with us in the number and value of their contributions to the medicine of the nervous system. In the current number of this quarterly many original articles may be found, amongst the best of which are:—A case of Spinal Hemianæsthesia and Hemiparaplegia (a fearful combination from a nosological standpoint) after Fracture of Dorsal Vertebræ, by Dr. Thomas M. Taylor; a case of Nodular Tumour of the Corpus Callosum, by Dr. Francis McGuire; a case of Tumour in the Optic Thalamus, by Dr. McBride. The editor, Dr. Spitzka, has abstracted many valuable articles from various European periodicals. A large amount of information has been given in the Proceedings of the Societies, and several books are critically reviewed.

New Inventions.

"APPUI" CHAIR BACKS.

NOVEL and useful inventions are the "appui" chair backs, giving elastic and yielding support to the spinal column, which can be regulated to the required position. No. 1 is composed of a steel spring about two inches wide, with a centre pad stuffed with horsehair, forming a soft cushion-like rest; the whole can be covered with stuff or cretonne to match the furniture; it will fit any chair. No. 2 is adjustable also, can be made more or less prominent, lowered, heightened, or placed at any angle, by means of a screw at the back of the pad. It is most suitable for a chair with a solid back. The apparatus is the invention of Mr. Moppett, Kemp Town, Brighton.

VENTILATING QUILTS.

MESSRS. BOOTH and FOX, of Cork, and Hatton-garden, London, have submitted to our notice a quilt which, to the qualities of lightness and warmth which are combined in an ordinary down quilt, add the advantage of admitting of efficient ventilation. This is provided for by the exclusion of the down from the double row of stitching which divides the sections of the quilt. The seams thus serve as excellent ventilators. The device is novel, and can scarcely fail of being effective.

"RECENT STUDIES IN BACTERIAL PATHOLOGY."

To the Editor of THE LANCET.

SIR,—In a leading article on the above subject in your issue of the 12th inst., you remark that "Falk has observed that putrefaction destroys the virulence of the tubercular virus," and that the same observer "has endeavoured to obtain by experimental means a benign tuberculosis by inoculating virus attenuated by putrefaction, with the view of discovering the means of vaccinating against tubercle."

It may be of interest to some of your readers to know that I have observed that the bacilli of tubercle are not destroyed, or even appreciably altered, by their continued presence in sputum which has undergone putrefaction. Thus, on the 14th inst., they were readily detected in laryngeal phthisical sputum which had been kept from August 10th last, now nearly a year ago. This sputum, originally muco-purulent in character, is now of a dirty milky consistence, with a strongly putrefactive odour, and scarcely any of its original constituents can be recognised by the microscope. The bacilli seem unaltered in their physical or chemical characters, with the possible exception of staining rather faintly with rosanilin—a feature, however, which is not unusual under certain circumstances with bacilli from recent sputum. Judged by appearances, they seem as capable as ever of communicating tubercular disease.

I am, Sir, yours, &c.,

Edinburgh, July, 1883. G. HUNTER MACKENZIE, M.D.

A MEMORIAL, praying the Lieutenant-Governor to call the Calcutta Corporation to account for its neglect of sanitation, has received over 1000 signatures, including those of the Chief Justice and Judges of the High Court, the Bishop of Calcutta, the Surgeon-General, and others.

THE LANCET.

LONDON: SATURDAY, JULY 19, 1884.

WE deeply regret to have to say that the Government are in danger of surrendering the most vital point in their Medical Bill, and we confess to feeling the utmost anxiety as to the measure. If there is one thing more than another which all medical reformers have desired, and for which they have laboured from the time of the founder of this journal till now, it is the creation of a single portal to the profession, through which all its members would have to pass. Whatever higher title they might attain, all were to pass through this one gate. The public is often duped with titles. Many bodies, even universities, have been well known to dispose of their highest titles on the lowest terms. There is nothing in a high title to guarantee a high examination. And many a meritorious medical man with humble title is placed at a disadvantage by a neighbour who has found medical authorities base enough to give him a high-sounding title on low terms in respect of everything but money payment. The Bill of the Government as originally introduced provided two or three safeguards against the trade in high titles. It provided that higher titles were only to be registered on condition of the Medical Council being satisfied that they were obtained after higher examinations than those for the licence to practise. This safeguard was abandoned last year. The Bill further provided—as every Bill for the last fifteen years has provided—for the creation of a single board in each division of the kingdom, the examination of which every medical man was to pass. The passing of this examination alone was to entitle the successful candidate to a licence to practise. Though a minimum examination, it was to be essentially a sound, honest, and disinterested one. As a common test, it was to try not only every student's work, but the work of the schools in which he had been educated, and incidentally the nature and stringency of the examinations of other bodies which he might have passed. It will not readily be believed that the Government is going to abandon this essential provision of their Bill and of all similar Bills. If they do so, they will deeply disappoint the profession.

The gentleman under whose persuasive eloquence they are said to have been induced to take this step is Sir LYON PLAYFAIR. The Government will make a great mistake if they attach too much importance to the somewhat cantankerous and warped views of Sir LYON PLAYFAIR. They should remember that he is not a member of the medical profession, and that the near approach of a general election, in which he is threatened with the loss of his seat, may explain his protesting so much about the interests of the Scotch universities. Sir LYON boasts of the number of his medical constituents. But he greatly mistakes the views of medical men if he thinks to advance his political interests, or those of the Government, by inducing the Government to abandon the One-portal system. Medical men will never forgive such a use of his, not medical, but quasi-professoria position in the House. Better far to be represented by a lawyer, by one who has no half knowledge of the profession, giving a false value to his views, than to be thus misrepresented. The more closely Sir LYON PLAYFAIR'S amendment is examined, the more does it appear full of most doubtful suggestions and statements: as that "the profession is undermanned," whereas almost every place is overstocked, the last year's Register containing several hundred more names than that of 1882; that "conjoint examinations alter the case and guarantee satisfaction to the State," whereas the greatest scandals brought to light by the inquiry of the Royal Commissioners have reference to bodies which have been acting conjointly for years; that the "creation of a sound and independent minimum examination will lower all examinations and make men more indifferent to higher degrees and distinctions," as if the raising of the basis of a pyramid could lower its apex; that "the highest professional authorities in the Commission were Mr. HUXLEY and Prof. TURNER," leaving Sir WILLIAM JENNER and Dr. MCDONNELL out of account as supporters of a Final Board; and that "the universities of Scotland will be injured and the demand for their degrees lessened by the creation of such an examination." How comes it that such Scotch graduates as Sir ANDREW CLARK, Dr. DUCKWORTH, Dr. SPENCER CORBOLD, and others, have besought the Government to pass their Bill? Seriously, Sir LYON PLAYFAIR is degrading the Scotch universities by representing them as afraid of such a small measure in the interest of the State; and he is sacrificing the interests of the medical profession, by whom hitherto he has been largely supported.

We have throughout supported the Bill of the Government. Not that it satisfies us. But in the present impotence of Parliament, and in the absence in it of even one medical man who can rise above the standpoint of the corporation interests of nineteen medical bodies—half of which are superfluous and need disestablishment—we were content to take it as a measure of reform. But if legislation is to become a mere piece of accommodation, if the Scotch and Irish bodies are to dictate their own terms, if effete bodies are to be perpetuated at the expense of the profession in the form of conjoint schemes, if the One-portal system is to be abandoned—then our interest in the Bill is gone, the surrender of Ministers is complete, and the incompetence of Parliament to deal with such a momentous question is well-nigh demonstrated. We look forward anxiously to Monday night, in the hope that Mr. MUNDELLA will see through the weakness of the platitudes and the plausibilities of Sir LYON PLAYFAIR'S amendment. In a very short time he could demolish them with his own strong common sense, and carry the House in support of the Final Board demanded by the profession, recommended by the Royal Commission, and accepted by the House of Lords.

WERE the matter otherwise of sufficient importance, it would be an interesting ethical investigation to discover what moral maxim, if any, underlies the action of the dominant party in the Council of the Royal College of Surgeons of England. It will be remembered that at the general meeting of the Fellows and Members, held in the College on March 24th last, a question was asked respecting the significance of a resolution of the Council. "Was it

Digitized by Google

not a fact that it had been held in the Council that a Resolution adopted by one Council did not bind another?" "Yes," said the President. "Then a Resolution of the Council may at any moment become a dead letter?" "Not unless it were distinctly rescinded," promptly answered the President; "and no rescission of a Resolution of the Council can take place without notice, argument, and confirmation. The Council really ought to be treated as gentlemen" (!) Pressed a little more closely, the President devised the memorable but confusing duplex classification of Resolutions of the Council—namely, first, "Resolutions which were intended to be directly *operative* when confirmed," and second, "Resolutions which were *not of an operative kind.*" It is necessary to bear this discussion and apology in mind if we would appreciate the meaning of a motion brought forward, after many postponements, by Sir SPENCER WELLS, at the meeting of Council held on the 10th instant, and referred to in our columns last week. Sir SPENCER WELLS proposed to move—"That all confirmed Resolutions of the Council be considered as in force until they have been formally rescinded, and that any existing Resolutions which are not binding on the Council be rescinded." This was at length divided into two parts. First, the Council was asked to pledge itself to the view that all Resolutions of the Council should be considered as in force until formally rescinded; in other words, that the Resolutions should in reality be directly "operative." This motion was negatived; hence it logically follows, in spite of the indignant remonstrance and protest of the ex-President, that all the Resolutions of the Council shall as heretofore be considered as *not* in force, and thus they shall all continue to remain in the category of "inoperative" Resolutions. The second part of Sir SPENCER WELLS' motion, "That all existing Resolutions not binding on the Council shall be rescinded," was withdrawn.

Now, what are the Resolutions which the Council has in times past deliberately adopted, but which it now, as always, with equal deliberation refuses to act upon? They are chiefly these:—First, that no one who has been twice elected a member of the Court of Examiners shall, at the expiration of his period of office, be eligible for immediate re-election. Second, that it is desirable that not less than one-half of the members of the Court of Examiners shall be Fellows who are not, and have not within twelve months, been members of the Council. Third, that the Minutes of each meeting of the Council shall be posted in the Hall of the College within five days of each meeting. The first of these Resolutions was adopted and *confirmed* eighteen years ago; the second and the third fourteen years ago; and yet we believe that not one has ever been "operative." As regards the first Resolution, it may be said that the present senior Vice-President is enjoying his third period of office in defiance of a *confirmed* Resolution of the Council. As to the second, it is enough to recall the fact that at the present time every member of the Court of Examiners is also on the Council, as well as one member of the Board of Examiners; while as to the third Resolution, we doubt whether, outside the Council, twenty Fellows and Members are aware that they are, by a *confirmed* Resolution of the Council, entitled to read in the Hall of the College the Minutes of the Council meetings within five days of the holding of such meetings. But when we remember how the Council to the very last persistently and wilfully disregarded a solemn obligation of a Charter respecting members of the Council who had ceased from the *bonâ-fide* practice of the profession of a surgeon, it is not difficult to account for the small value it sets on its own resolutions.

ALTHOUGH cholera has spread to some few outlying places in France, yet the disease is still limited as an epidemic to Toulon and Marseilles; but in both these towns the average daily number of deaths has undergone an increase since last week. This is especially the case as regards Marseilles, where the deaths have for some days past varied from about fifty to seventy. What is in store for France and for Europe cannot as yet be foretold. Twenty years ago, when Marseilles received the cholera infection from Alexandria, it infected the rest of France, and before France admitted itself as infected, Valencia had received a serious amount of infection through it, and through Valencia all Spain became involved. The policy of concealment, which has so largely influenced the attitude of those who are in authority in France, is the least hopeful feature of the subject, and it is probably to this attitude that some of the rumours as to the spread of the scourge are due, for the people themselves cannot believe that the Government allow the whole truth to be known.

The Academy of Medicine has wisely decided against any attempt at an inland quarantine and sanitary cordons, deeming such measures to be impracticable in a commercial and populous country like France. They have also entered a protest against the futile and vexatious processes of so-called disinfection to which people are subjected on entering Paris and other towns. This is a wise step, and it is to be hoped that the energy which has been thrown away in this direction will now be devoted to general sanitary measures, which, by the removal of conditions of filth, will make the towns and villages to which the infection may be brought less susceptible of the disease. The danger as regards secondary cholera centres may be more and more removed as the adoption of adequate sanitary measures shall bring within control the conditions which usually lead to the spread of what are known as filth diseases. It is also on these measures that we must ourselves rely in case infection is imported into this country; and it specially behoves the sanitary authorities of ports and towns in frequent communication with France to set their houses in order from this point of view, and so to hold themselves in readiness both as regards the removal of filth and the provision of means of isolation that they will at once be prepared to face any emergency. Scares are sure to arise, and the majority of them will be either altogether or nearly unworthy of credit. One has passed quietly by this week. The *Carthagena* has arrived safely at its Welsh port, the few men who were recovering from choleraic diarrhœa have been isolated, and the danger is apparently over.

During the past few days cases of so-called cholera are alleged to have occurred in London. That they were not instances of the genuine disease is tolerably certain from the subsequent history of the places and families in which they arose; and we cannot too forcibly urge medical practitioners to be careful as to the diagnosis which they may make when called in to treat cases of severe diarrhœa.

Digitized by Google

such as always occur in the metropolis during the hot summer months, and which are so often misnamed cholera. At the present moment the right course is to adopt the strictest preventive measures as regards isolation and disinfection with respect to every case that may present doubtful features, and it will be policy in all such cases to communicate with the local medical officer of health; but it is at the same time no less important not to create a panic by proclaiming a case to be cholera merely because it is fatal and has been accompanied by some of the signs of the epidemic disease. Some of our neighbours have already lost their heads; during, at least, one of our previous epidemics of cholera people in this country did the same thing. It will be well to learn by experience, and to remember that in the face of a common danger every member of the community has a definite duty towards his neighbour, and this duty he will certainly not accomplish by running away and so tending to increase a panic. There is still time for householders to disconnect their houses from the drains, to secure a current of air through all house drains, to remove all offensive appliances, fittings, and accumulations, and to see that water cisterns are clean and overflow into the open air; and having done this they may, by the observance of the most ordinary precautions, remain where they are, at a risk which is but trivial compared with that which many are now running because they have not abolished from their homes conditions favourable to the spread of some of our current but very fatal preventable diseases.

THERE seems no improvement in the lamentable condition of affairs that for many months has distracted the inhabitants of the Diamond Fields. The Kimberley Board of Health, having expended over £16,000 in the attempted suppression of a singularly fatal epidemic, finds itself in pecuniary difficulties. Nor is this to be wondered at when one considers that the great mining interest which represents the main source of income to the districts of Kimberley, Beltfontein, and Dutoitspan has been led by what we venture to think the mistaken policy and action of certain medical men. Surely it ought to be sufficient to convince the most sceptical that a mortality of twenty-two out of fifty-three cases has obtained in one district alone—the native location in the division of Hay or Herbert. What does it matter to the victims whether the plague of which they suffer and die is small-pox or "a disease allied to pemphigus," or the still more problematical "varicella hæmorrhagica"? We have already explained our firm conviction that there has been a visitation of genuine variola, notwithstanding Drs. JAMESON and WILLS have declared to the contrary. In the *Cape Times* of June 10th is the doctors' report from Griqualand West. It is there stated that, whilst the epidemic is causing great alarm in Kimberley, Dr. WOLFF, one of the surgeons to the sanitary boards, winds up a report with words to this effect: "The disease is a miasmatic one (like malaria), and *not* contagious; and the isolation of a hospital is hardly necessary, and the destruction of suspected contagious fomites is a needless expense." Can it be matter of surprise that the local executive authorities find their work brought to a dead-lock when they are confronted with such compromising professional opinion? A general idea of the confusion that prevails may be gathered from the fact that at a meeting of the Beaconsfield Town Council the following question was formally put to the members: "Is the disease 'small-pox' or 'so-called small-pox'?" It says something for the sagacity of these gentlemen that by a large majority they voted in favour of the latter description of the pestilence. We see it is recommended that a commission composed of leading medical men in Cape Colony should determine the point in dispute. Certainly a competent official tribunal ought to investigate the whole matter; for as it stands at present, it is a scandal and a disgrace to the medical profession, and a source of immeasurable mischief to the community. Cannot the Secretary to the Colonies see his way to sending out a skilled and unbiased observer to examine and report on the nature of the outbreak?

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS.

IN our report last week of the meeting of the Council of the Royal College of Surgeons of England held on the 10th inst., we inadvertently omitted to state that Mr. Heath's motion, "That at the ordinary meeting of the Council in November next, the Council do consider the mode of electing the President and any alterations suggested in the method of proceeding in the election," was carried *nemine contradicente*. At the meeting in November Mr. Heath will be prepared to present a scheme for electing the President, and it may be confidently assumed that this scheme will not only depart from the existing absurd system of electing the President by rotation, but that it will provide for the election in some such way as that suggested in a recommendation adopted at the general meeting of Fellows and Members held at the College last March.

DIARRHŒAL MORTALITY IN ENGLISH TOWNS.

THE outbreak of cholera in the south of France invests the usual advent of summer diarrhœal fatality in our English towns with more than the usual amount of interest. Although May was exceptionally warm, the mean temperature and the amount of rainfall in June differed but slightly from the average, and the deaths attributed to diarrhœal diseases in the English towns during June were very considerably below the corrected average. In London, for instance, the recorded deaths from diarrhœa and dysentery in the four weeks ending June 28th were only 95, the corrected average number in the corresponding period of the ten years 1874–83 being 177. The materials for a similar comparison as regards the mortality from diarrhœa and dysentery in the twenty-seven provincial towns are not available, but for present purposes it is enough to state that the diarrhœal mortality during last month was also below the average in these towns. At the beginning of the present month, however, concurrently with a marked increase in the temperature, the mortality from diarrhœa showed a rapid increase. The deaths referred to this cause in London, which had been but 21 and 39 in the last two weeks of June, rose to 104 and 336 respectively in the first two weeks of July, the latter number exceeding the corrected average number in the ten preceding corresponding weeks by 115. In the twenty-seven provincial towns the deaths from diarrhœa also showed a marked increase, but the increase was not nearly so great as that recorded in London; they were 34 and 51 in the last two weeks of June, and rose to 71

Digitized by Google

and 159 in the first two weeks of July. With reference to these figures, it may be stated that the aggregate population of the twenty-seven provincial towns is slightly greater than that of Registration London, and that summer diarrhœa fatality has in a long series of years almost invariably shown an increase in London prior to the recorded increase in the provincial towns. With regard to the recorded mortality from diarrhœa in the second week of July, it was equal to an annual rate of 2·9 per 1000 of the estimated population of the twenty-eight large English towns; in London the rate was equal to 4·4 per 1000, whereas it did not exceed 1·7 in the twenty-seven provincial towns. Among these provincial towns the diarrhœa death-rate showed a marked divergence. No death was attributed to this cause either in Sunderland, in Derby, or in Halifax; while the highest diarrhœal death-rates were 2·3 in Norwich and Birkenhead, 2·6 in Salford, 3·1 in Preston, 3·8 in Bolton, 3·9 in Leicester, and 6·1 in Nottingham. It should be noted that 25 deaths in the twenty-eight towns were also attributed to choleraic diarrhœa, or cholera, of which 16 occurred in London and 9 in the provincial towns; a certain number of deaths are so attributed every summer, and the number above-mentioned, as regards its proportion to the recorded diarrhœa deaths, is below the average.

THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

IN May last it was suggested by THE LANCET to make the new wing of this hospital now rebuilding in Queen-square a memorial to the late Duke of Albany, and the consent of the Queen having been cordially given to the proposal, no time has been lost in taking action upon the suggestion. A public meeting was held at Willis's Rooms on Monday last, which was worthily presided over by the Earl of Shaftesbury, and at which resolutions embodying the idea were passed. The resolutions were supported by Sir William Gull, Mr. Carter, Mr. Hutchinson, Lord Denman, Canon Fleming, and others. Of especial interest and significance was the presence of Mr. Arnold Royle, C.B., the Duke's medical attendant, who in a few well-chosen sentences adverted to the intense sympathy ever felt by the late Prince towards any movement which had for its object the alleviation of human suffering, and warmly endorsed the object for which the meeting was held. Between £2000 and £3000 were subscribed by those present. We understand that the rebuilding of the hospital has been making rapid progress since last autumn; and great hopes are entertained, if money can be obtained, that a commodious hospital may be completed in the course of next summer.

SECONDARY SUTURE OF THE MEDIAN NERVE.

AT a recent meeting of the Academy of Sciences M. Tillaux related two cases of secondary suture of the median nerve followed by rapid restoration of the functions in the parts depending upon it. The first was a young girl who cut the front of her wrist whilst cleaning some windows in November, 1883. The wound healed without suture of the nerve being performed, and there remained complete paralysis of all the parts supplied by it. Incapable of working, the girl went to the Beaujon Hospital to seek relief. The parts supplied by the median nerve were found to be colder than on the opposite side, and of a slightly violet colour. Notwithstanding the discouraging nature of the case, M. Tillaux decided to give the patient a chance. The ends of the nerve were found about a centimetre distant from one another, the central one bulbous, the peripheral atrophied. They were cut so as to present a fresh equal surface and carefully drawn together by a hair suture (*crin de Florence*). An antiseptic dressing was applied and the limb immobilised in extreme flexion. Two days after the operation sensibility began to return and increased daily. Six weeks later she left the hospital with sensibility and movement entirely restored. The other patient was a woman who, witnessing the result in this case, begged M. Tillaux to operate upon her also, notwithstanding that the accident had occurred fourteen years before. The operation was identical, and the next day sensibility began to return, and was soon entirely restored. The physiological curiosity of these cases lies in the fact that when examined microscopically (by M. Ranvier) the portions of nerve removed exhibited no trace of cylinder-axis, and that it is difficult to explain the restoration of function by our present ideas on the subject. M. Tillaux's observations may be the starting-point of an important discovery.

THE PRESERVATION OF COMMONS.

THE need for the existence of the Commons Preservation Society has been abundantly proved in the history of litigation during the last few years. The success which has attended the efforts of the Society is a public benefit of the most fruitful kind. A common is something more than the official public garden. It has advantages which the latter has not. It affords not only fresh air and an undiluted share of what sunshine there may be, but a place for the free exercise of muscle under those very helpful conditions. Nor must it be forgotten that commons are in their way teachers, and that their lessons, as valuable as any others, cannot well be learnt in schools. The lover of nature, if he is careful to observe, finds in them much intellectual profit and amusement. His opportunities in this respect have unfortunately already undergone serious reduction, since nature in many districts has been nearly effaced by the town. The spreading edges of cities approach one another more and more nearly, the contagion of building occupies the intervening areas, and the country is rapidly being converted into a smoky town-tract. It is certainly as unwise as selfish, then, to grudge to recreation a piece of land here or there which the forethought of an earlier time has assigned to that purpose. Yet this is what railway companies and rich private persons are equally prone to do. With them the convenience of wealth admits no prior necessities, and conditions of public health are mere pedantic theorisings. It is true, notwithstanding, that the care with which we guard the means and places for suitably using leisure time will go far to decide whether our material prosperity, as it increases, shall exhaust us by universal toil, or shall carry with it an equal degree of national vigour, with promise of even greater attainments.

GLOUCESTER INFECTIOUS HOSPITAL.

THE Gloucester urban sanitary authority seem singularly averse to take the action which they should do as regards the isolation of the infectious sick. Last year, in consequence of the very imperfect character of the existing arrangements, Dr. Thorne Thorne conferred with the urban and rural sanitary authorities on behalf of the Local Government Board, and urged combination in the erection of a proper hospital. The rural authority appear willing to take this step, but the urban authority prefer spending money on a temporary building which has already been condemned. The medical profession have now joined in a protest against this parsimonious action, and they have appealed to the central authority for support. For years past the existing building, which we believe was one of the many truly structures erected during a period of panic, has been regarded by the profession as practically useless, and since only one infectious disease can safely be received into it, they have

Digitized by Google

not dared to send in patients lest another disease should happen to be under treatment there at the same time. What is wanted is such a scheme as will secure the erection of at least two separate pavilions, one of which should be an isolation building, such as we recently referred to as intended to be erected at Bournemouth. In this way the needed first requirements of the district would be met, and the accommodation which the town would require would probably in the first instance suffice also for the needs of the adjacent rural district, and hence combination would result in considerable economy, whilst increased efficiency would be secured. It is much to be hoped that the Town Council will be advised in this matter by the medical practitioners who have counselled them aright, and who, whilst knowing the sanitary requirements of the city far better than many members of the corporation can do, have as deep an interest in the prosperity of the city as any other inhabitants, be they in authority or not. Gloucester has suffered serious mortality from infectious diseases whilst the present hospital has remained all but empty; so serious a state of things should never be allowed to recur.

DEATH OF DR. W. G. BALFOUR, OF BOMBAY.

IT is with deep regret that we learn the sudden death, from apoplexy, of Dr. W. G. Balfour, which took place in Bombay on Sunday morning, June 15th. Dr. Balfour, who received his medical education in Edinburgh, had for some years devoted himself to the specialty of lunacy, in which he had acquired considerable practical experience; but, owing to circumstances, he gave this up and went out to India in the capacity of surgeon to the Great India Peninsular Railway Company, and subsequently settled in Bombay in private practice. The deceased gentleman was a good microscopist, and has contributed some valuable papers to these columns, mostly in connexion with cholera and the cholera germ. Like the German *savant*, Professor Rudolph Emerich, he not long since drank a concentrated solution containing cholera excreta by way of experiment. He leaves behind him a family at home in Scotland to mourn their loss.

REMOVAL OF PATIENTS FROM HOSPITAL.

A VERY interesting question relating to the removal of patients from infirmaries and such institutions has been raised in Glasgow by the publication of a letter from Sheriff Spens in the *Glasgow Herald* of Monday last, in which he states that he has found, to his surprise, that in both the infirmaries it is thought the officials are bound to hand over patients on the demand of the natural guardians or relatives, to be removed to their homes, although it is known that such removal will cause extra risk to the patients, and may even be certain death. Sheriff Spens gives it as his opinion that the infirmary authorities are mistaken as to their being under any obligation to hand over patients to relatives on demand where it is known that the removal over the rough streets will of necessity be fatal or even injuriously affect the chances of recovery. The primary duty which the infirmary authorities are entrusted with is one to the patient and not to the relatives, and that duty they are entitled to defend against all. They have become the temporary guardians of patients for the purpose of curing them; and it appears to Mr. Spens that no court of law would for a moment give countenance to the view that there was a higher right in a guardian or a relative to demand delivery than in infirmary authorities to refuse on the ground of obvious risk to life. The force of this strongly expressed opinion is apparent, but its validity is not so obvious. Are we to understand that in an infirmary the medical attendant is not simply the adviser of the patient, as he would be regarded in private practice, but is also his responsible guardian? Or do the authorities, lay and medical, step into the position of "natural guardians" of the infirmary patient? This is not a mere matter of professional etiquette, but rather one affecting the liberty of the subject; and it is one which demands very prompt settlement. The distrust of hospitals among the ignorant poor is great enough, and would be increased tenfold if these institutions were endowed with such powers as Sheriff Spens indicates. Pending the settlement of the question, and till further instructions are issued, the secretary of the St. Andrews Ambulance Association has directed his officer "to be guided on all occasions by the opinion of the officials in charge, and to refuse to undertake removals which they consider dangerous."

QUARANTINE AND THE FORTHCOMING CONGRESSES.

THERE appear no grounds for apprehending that any measures of quarantine will in any way affect the attendance at the forthcoming Medical Conferences at the Hague and Copenhagen. Neither the government of the Netherlands nor that of Denmark has followed the example of Spain; and in view of the example set them by Germany, which is willing to follow very much the lead of England in this matter, it is highly probable that our own system of inspection and subsequent isolation of those actually sick may be carried out in the case of the two countries referred to, should real danger of cholera importation arise. Both Denmark and the Netherlands seem desirous of excluding small-pox quite as much as cholera, but if any action should be taken for this purpose it will probably be limited to an inspection of persons entering the country by sea merely with the view of placing under isolation any who are found to be suffering from infectious disease. Such a system should in no way interfere with the attendance at either of the Congresses mentioned.

"THE DROWNING SEASON."

IT must, we presume, be accepted as a general proposition capable of particular application in the most vexatious directions and specialities, that any and every sport, exercise, and pastime which involves a certain amount of personal risk will have an inevitable attraction for English folk of all classes and ages. On no other principle is it possible to account for the curious fact that, although year after year many lives are ruthlessly and uselessly sacrificed in such practices as bathing, boating, hunting, and skating, no lover of these several pursuits is deterred from indulging in them by the peril incurred. On the contrary, it is beyond question that this very peril adds zest to the pastimes. When, therefore, we encounter a paragraph in the press under the above ominous heading giving particulars of eleven deaths by what are, almost facetiously, termed "accidents" in the course of a few days, we do not dwell long on the mournful epitome, but pass it over with something of the same feeling as may be experienced on reading the bare statistical statement of a death-rate. Nevertheless, it is a grim fact that every one of these lives might have been saved by a little timely precaution. Either the bath was taken in too deep water or at an unsuitable spot, or there was some neglect of obvious measures and conditions of safety. Nothing would be gained by reiterating the warnings we have repeatedly given as to sudden plunges into cold water, if the heart be weak, or there be a tendency to cramp; as to severe trials of strength in buffeting with heavy waves or trying to swim long distances; and as to going into the water weak or exhausted by want of food, or with a stomach so loaded that disturbance of the circulatory and nervous systems must almost inevitably ensue if there be even a moderate amount

Digitized by Google

of congestion set up by the immersion in a fluid colder than the atmosphere. These and a score of other dangers arising out of, or dependent upon, states or diseases of the organism, have been pointed out and the importance of caution insisted upon. We preach to heedless ears. Tell an English man or boy that anything is dangerous, and he will burn to do it. If he be weak, he will try to behave as though he were strong. If he be unfit, by reason of physical disability of some sort, for a particular exercise, he will yearn, above all things, to do the impossible and to hazard the extremely perilous. In health he will scorn safeguards and precautions as signs and tokens of cowardice. We do not think that mere carelessness is so common as some people are apt to suppose. We believe it is downright foolhardiness that leads to "accidents" of the class represented as "deaths by drowning." This is an important consideration, and it is one that must to some extent modify what we have to say on the subject of the "drowning season" year by year. The accidents that occur are deplorable, it is true; but, on the whole, it is more honest to say that they are discreditable, and it is high time to have recourse to plain speaking. Pity must give way to reproaches, even though it be necessary to violate the rule that nothing but good should be spoken of the dead.

ACUTE ALCOHOLIC POISONING.

AN inquest was held at Royston on July 1st touching the death of a little boy named Enderby, aged nearly four years. The father of the deceased found him insensible at half-past ten o'clock in the morning, breathing stertorously, and smelling of spirits. It appears that a bottle of brandy was kept in a box in the bedroom, and to this the unfortunate little fellow gained access and regaled himself with the contents. Convulsions succeeded the coma, and death ensued about twenty-four hours after the onset of the symptoms. There was no smell of alcohol in the contents of the stomach ejected after an emetic was administered in the course of treatment. This, however, does not negative the supposition that death was due to alcoholic poisoning, for Taylor gives a similar case in which a pint of spirits was taken, and a fatal effect produced eight hours afterwards. Investigations, both on the human subject and on animals, have shown that the poison may be detected in the blood and viscera a considerable time subsequent to all traces of it having disappeared from the stomach. In the case under notice it is believed that half a quartern of neat brandy was swallowed—an amount quite sufficient to account for the results. From a toxicological point of view, it is a pity that no post-mortem examination and analysis were made, although there seems no reason to doubt the accuracy of the assigned cause of death. Acute alcoholic poisoning is not of very rare occurrence, since Taylor mentions the fact that thirty-five cases were registered in four years in England and Wales. There is no specific physiological antidote to alcohol. The treatment aims mainly at removing what remains in the stomach; keeping up the body temperature, which always shows a marked depression; and administering readily absorbable nourishment. The last-mentioned item is of the greatest importance, since to the toxic action of the poison is superadded the asthenia consequent on privation of food. Our experience does not lead us to concur in the view expressed by the coroner, "that the child must have in some extraordinary way acquired a taste for brandy." Children have a natural tendency to imbibe whatever comes in their way, as the records of violent deaths too fully prove. For example, it could scarcely be contended that because a child swallowed some of the contents of a kettle of boiling water the act showed an appreciation of the results of previous indulgence, and yet this accident is not at all uncommon. There is one lesson to be learned from the sad event described above—viz., that those who have the charge of children should take care that all deleterious liquids are kept in safe custody.

THE COUNTRY HOLIDAY FUND.

ONE of the happiest developments of business habit has been the general application of method in projects of benevolence. The unobtrusive visitations of many true friends of the poor, unnamed perhaps in public, have had much to do with this result. They have kept open the communication between rich and poor, and have taught the wealthier class who of their less favoured brethren deserve their help, and how that help should be given. It will readily be admitted that the "Country Holiday Fund," for the benefit of London children, is one that merits the support of names distinguished in philanthropy which it has received, but which alone can cover but a part of its requirements. The name of the Fund fully describes its purpose, and pleads its own cause almost better than any more elaborate explanation. Lord Rosebery, in an exact and comprehensive speech at the Mansion House on Monday, dwelt on the affinity between the mind of childhood and the natural country, on the benefit to health from their association, and on the public good which must accrue when every class combines to further an object so humane. No one who knows the tender life of children, and how it thirsts—plant-like—for pure and wholesome conditions, can question that these observations are true in every word, or can doubt that a week or two of country, to many a luxury, is to them other than a vital necessity.

THE THAMES.

IT was felt while the Royal Commission on Metropolitan Sewage Discharge was sitting that some of the evidence given was exaggerated, and that the pessimist view taken of the matter by the medical officer of health for the port was scarcely justified by the facts. Unfortunately, however, the decision arrived at by the Commission has during the recent hot weather been far more than justified. It is no exaggeration to say that the whole river from Greenwich to Greenhithe has been full of sewage. The colour of the water is black and the odour intolerable. Such a state of things has naturally caused much anxiety. The Port of London Sanitary authority, alive to the danger, has addressed the Local Government Board, pointing out the necessity for immediate action. As a consequence pressure has been brought to bear upon the Metropolitan Board of Works, who have tardily agreed to the deodorisation of the sewage before it reaches the outfall. This, however, can merely be a palliative measure, the only real remedy being to remove the outfalls many miles further down.

SMALL-POX IN NEWCASTLE.

ON the 10th inst., at the Newcastle-on-Tyne police-court, a woman who carries on the trade of a cowkeeper and milk retailer was charged with having neglected to give notice to the medical officer of health of the existence of small-pox on the premises occupied by her. It was stated that the milk from two cows and the milk-vessels were kept in the one room where the defendant, her daughter, and two children lived and slept. The milk was carried to the house from the cow-byre and strained, and was afterwards retailed by the defendant. On March 11th a neighbour saw that one of the children was suffering from small-pox, and told its mother that she ought to report the case to the medical officer of health. On April 16th the medical officer went to the house and saw the girl, who was then

Digitized by Google

convalescent, but showed evidence of having had a very severe attack of small-pox. The child had been prescribed for by a chemist, who, however, had never seen it. In the yard in which defendant lived this was the first case of small-pox, but since then there have been four cases, and one, that of the head of the family, has proved fatal. The magistrates imposed a fine of forty shillings and costs, the full penalty, and expressed the wish that the greatest publicity possible should be given to the case. It is unfortunate that such an offence should not entail imprisonment without the option of a fine, a monetary penalty being wholly inadequate to the gravity of the case.

THE BROMPTON CEMETERY.

ON July 2nd we published a letter describing the state of the Brompton Cemetery, and showing in our opinion good reason for its disuse as a place of burial. This cemetery, and also one or two others in the east of London, no longer occupy their original position on the margin of the city's growth, but lie well within its ever-widening limits. The modes of burial are no better than elsewhere, and are such as we have frequently criticised unfavourably. The choice of soil, sand and gravel, has not been a happy one. Sand has no doubt a certain advantage in its porosity, but it does not favour the processes of oxidation which ought to go on in the buried body, and so rather hinders than helps the due restoration of earth to earth. In warm weather, such as we have lately experienced, the evils of organic contamination must be doubly felt. Their influence cannot but be magnified when they are generated in a soil like sand, which readily absorbs and radiates heat, which but feebly assists chemical change, but wants nothing to enable it to nourish the living germs of putrefaction.

HEALTH EXHIBITION.

THE *fête* to be given on the evening of the 23rd instant in aid of the London Hospitals promises to be a very gay and attractive affair. The Prince and Princess of Wales have both promised to attend, and nothing will be omitted which is likely to give *éclat* to the proceedings. Military bands will be provided to the number of three or four, and we believe that a special orchestra has been engaged to play in "Old London." The Water Companies, under the direction of Sir Francis Bolton, are conspiring with the Electric Lighting Department to make the illuminated fountains more than usually attractive, and the Chinese Restaurant, which is now in full working order, may be expected to form a special centre of attraction. A committee of ladies has arranged for the erection of a number of stalls, each of which will be presided over by ladies of social distinction and at which fruit and flowers will be sold; but beyond this there will be no bazaar element in the display. All who have visited the Exhibition are agreed that its appearance of an evening is unequalled, and most of the foreign jurors and commissioners who are over here admit that their various countries can show nothing like it. "'Tis a dream from the Arabian Nights," said one; and so it is. And we can only hope that the British public will remember that next Wednesday, when they visit the Exhibition, they will not only be seeking enjoyment, but indirectly helping to alleviate the sufferings of their less fortunate brethren. We heartily hope that the hospitals may have what in "theatrical parlance" is called a bumper benefit, and that the Executive Council may find their doors thronged to the utmost.

CONVALESCENTS FROM SCARLET FEVER.

THE Home established by Miss Mary Wardell for scarlet fever convalescents, at Brockley-hill, Stanmore, was opened by the Prince and Princess of Wales on Monday last. Miss Wardell's great credit in this undertaking is enhanced by the pleasing announcement that so far the committee are not in debt. The Prince seems never more at home than in acts of practical philanthropy, and as usual made a very apt speech on the occasion. We heartily congratulate Miss Wardell on the great amount of influential sympathy already experienced, and wish her entire success in her arduous and benevolent undertaking.

THE PORT OF LONDON: CHOLERA.

IN view of the possibility of the importation of cholera from Marseilles the precautionary measures adopted in the Thames in 1883 have been scrupulously maintained. The only vessels which arrive regularly direct from Marseilles are the Peninsular and Oriental, the Messageries Maritimes, and the Trieste boats, and these are all receiving special attention. Dr. Collingridge has moreover made arrangements for the medical inspection of every vessel entering the river in the event of any serious spread of the epidemic rendering such a course advisable.

FOOD ADULTERATION AND ANALYSIS.

UNDER the auspices of the Institute of Chemistry a most important conference on adulteration, which seems likely to lead to valuable results, has just been held at the Health Exhibition. The opening paper was by Dr. James Bell, F.R.S., of Somerset House. The discussion lasted over two afternoons, and many well-known chemists took part in it, as well as several gentlemen who represented the trading interest. We give in another column an abstract of Dr. Bell's paper.

LOWER THAMES VALLEY SEWAGE.

THE Select Committee of the House of Commons have rejected the scheme of the Lower Thames Valley Main Sewerage Board, and recommend that the district shall be divided into four or five districts, each of which shall purify and dispose of its own sewage. The decision is a most important one, and we shall shortly offer some remark upon it. There is no doubt as to the urgency of the question, for the present condition of the river is a most serious danger to London. The letter of Sir Thomas Nelson, which appeared in the morning papers the other day, will increase the alarm generally felt.

MR. GAY, F.R.C.S.

WE regret to announce that Mr. Gay's state of health is such as to give his friends very great anxiety. About Christmas last Mr. Gay found himself rapidly becoming unequal to the fatigues of his professional duties, and a few months later he was compelled by increasing physical weakness to relinquish all active work. From time to time hopes have been cherished that with genial weather a measure of health and strength might return, but unfortunately these hopes have not been realised.

THE danger of disease being disseminated by means of imported rags is very patent. The Hull Sanitary Authority is properly concerning itself with this matter in reference to shipments of rags, and it is certainly desirable at the present time that extra precautions should be taken. A cargo of these objectionable articles having arrived from Marseilles, the ship was boarded by the Hull port sanitary officials, detained and thoroughly disinfected, the cargo being transhipped and submitted to disinfection. A few days since a large consignment of rags from Marseilles was landed in the Royal Albert Dock, London. They were at once detained by the medical officer of the port, and will be thoroughly fumigated by the superheated steam process.

Digitized by Google

THE following is the programme of the Conference of the Epidemiological Society of London at the International Health Exhibition to be held on the 22nd and 23rd of July, 1884. President, Dr. Norman Chevers; Hon. Secretary, Mr. Shirley Murphy:—July 22nd, at 2.30 P.M.: The President's opening address on Health in India; Dr. Squire on the Change of Type in Epidemic Disease. 23rd, at 11 A.M.: Surgeon-General Pringle on Leprosy in India, and the best means of Preventing its Increase; Mr. Barrington Kennett on Floating Hospitals, with a view to showing their Efficacy in Checking the Spread of Epidemics. At 2.30 P.M. a Consideration of the Present Aspect of Cholera in Europe will be opened by Inspector-General of Hospitals Robert Lawson, M.D.

WE hear that Dr. Donald MacAlister is a candidate for the post of Physician to Addenbrooke's Hospital, Cambridge, rendered vacant by the retirement of Dr. Paget. Dr. MacAlister for some time past, we believe, has seen Dr. Paget's out-patients, and at times has taken charge of his wards. As is well known, he had a most distinguished academical course, and has shown ability as marked in the pursuit of medicine as in that of mathematics. He is strongly supported in his candidature by the members of the staff at Addenbrooke's Hospital, and we should imagine that his appointment is certain.

WITH the view of preventing the importation of cholera into the United States, telegraphic instructions from Washington have been received at the American Consulate-General in London to appoint medical inspectors to examine all vessels sailing from London and Liverpool for the United States of America. The Consul-General has accordingly appointed Dr. J. Higham Hill health inspector at London.

THE managers of the Metropolitan Asylums District have found it necessary to enlarge their camp at Darenth for convalescent patients from small-pox, so as to accommodate some of the less severe cases for which room cannot be found in the hospitals and hospital ships. The managers have purchased a river steamer called the *Marguerite* to convey passengers to and from their hospitals.

THE condition of the River Lea is causing disquietude. Dr. Tripe has called the attention of the Hackney District Board of Works to the dangerously foul state of the stream, and the Poplar Board has resolved to serve the Lea Conservancy Board with a notice to remedy the evils which are but too conspicuous.

PROFESSOR TYNDALL has promised to preside on Tuesday next, at 5.30, at a lecture at the Health Exhibition, to be given by Dr. G. V. Poore, on "Thrift in its Relation to Health; the Right Use of Refuse."

THE Glasgow Town Council have caused regulations to be put in force for the purpose of preventing the entrance of cholera, and for the treatment of persons who may be attacked with the disease.

FROM Sheffield comes the report of the death of another medical man, Mr. Morris, formerly surgeon in the army, from an overdose of that treacherous drug, chloral hydrate.

SMALL-POX has broken out at the Spital cavalry barracks, Windsor, and a fatal case is also reported to have occurred among the troops stationed at Aldershot.

THE MEDICAL ACT AMENDMENT BILL.

AT a recent meeting of the Senate of the University of London, Sir Lyon Playfair's amendment was discussed, and a deputation, consisting of Sir J. Paget, Sir J. Lubbock, Sir W. Gull, Dr. Quain, Dr. Storrar, Mr. Wood, LL.D., and Mr. Shaen, was appointed to wait upon the President and Vice-President of the Council to point out to them the objectionable nature of that amendment. The deputation believed it to be contrary to the spirit of the Bill, and that if adopted, the evils which it was desired to remedy would be aggravated. Lord Carlingford said the chief aim of the Government was to secure uniformity and completeness of qualification in candidates for the medical profession, and he believed that end would be accomplished by the Bill. The Government also conceived that greater power would be given to the reformed Medical Council, and, further, that under a system of joint examiners, appointed by the Medical Board, uniformity of qualification would be secured. The deputation, dissenting, maintained that neither the power of the Medical Council nor the confidence which might be reposed in the conjoint examiners would be sufficient to secure the object aimed at in the original Bill. During a long discussion, it was suggested that the objects of uniformity of qualification and examination might be ensured by the appointment of assessors, who could visit and report on the manner in which the examinations were conducted. This suggestion, originally made by Professor Turner, a member of the Royal Commission, seemed to be viewed with favour by the President and Vice-President, and the deputation, having thanked the Ministers for their courteous reception, then withdrew.

THE INTERNATIONAL HEALTH EXHIBITION.

THE FRENCH SECTION.

[FIRST NOTICE.]

THE French have strictly adhered to the spirit and principles that might be expected to govern a sanitary exhibition. Once within the French section, the visitor feels that he has around him the silent testimony of earnest study, all strictly bearing on health and education. The bazaar element and trading interests are all strictly excluded, and may only be found outside the walls of the enclosure which forms the principal portion of this section. Within this inner temple, the great problems that have been so ardently debated among specialists on the other side of the Channel, and the sanitary progress attempted and accomplished during the last few years, are fully illustrated by the exhibits, which are skilfully grouped. A comprehensive catalogue alone is wanted. The details given in the English catalogue are altogether insufficient, and there are no numbers to enable the visitor to find the objects he wishes to examine. The town of Paris, however, publishes an admirable catalogue of its own exhibits, which occupy half of the entire court.

Holding the place of honour in the centre of the section, the very complete exhibits of M. Pasteur give a history of his researches and discoveries. The descriptions both in English and French that are attached to each object are of great aid, for it is not always possible to guess the precise use of a flask or the liquid it may contain. When M. Pasteur's assistants, Dr. Roux and Dr. Chamberland, were in London, they always commenced their explanations by pointing out the cardboard models of the left and right hand crystals of tartaric acid. It was the discovery that microbes were developed more rapidly with the right hand crystals which led up to many of M. Pasteur's subsequent and successful investigations. Next to these crystals is the historic and large vessel charged in 1861, and which still contains unaltered the production of a fermentation of

Digitized by Google

200 grammes of sugar acted upon by a minute particle of yeast that had been deposited in a mineral medium. The purity of the yeast and the previous sterilisation by heat, practised, at the very onset, explain the success of the operation. From this dates the use of sterilised liquids or pure cultures. In front of this celebrated experiment is a double row of flasks or glass "balloons," which were opened on the summit of Montanvert in 1860, and the culture broth they contained has remained pure ever since, with the exception of two bottles which were accidentally broken in descending near the foot of the mountain. In two little bottles, close at hand, there are specimens of blood drawn from the heart of a rabbit which has remained pure after many years, and of unaltered serum of bullocks' blood gathered *in vacuo* in tubes purified by fire, but kept without heating. Taking a step further to the right, we come upon a number of tubes, flasks, &c., used for cultures *in vacuo*, with some tubes containing vaccine for anthrax; and one hundred doses for sheep and fifty for bullocks are held in tubes of the same size. There are also specimens of liquids sterilised by cold, and in the background statistical tables giving the practical results attained in the prevention of splenic fever among cattle. The eastern side of the table is occupied with stoves used for cultures, and methods of indicating and automatically maintaining a given temperature within the apparatus. In one of these, constant temperature may be regulated to the tenth of a degree Centigrade, and there are steam coils to surround the funnels holding filtering-papers, warmed plates to stand cultures upon, and gauges for gas pressure &c. On the north side will be found instruments used for inoculation. One especially ingenious contrivance contains the vaccine in the handle, which can be squirted out at a regulated dose so rapidly that it is possible for one man to inoculate two thousand sheep in one day. But, to the general public, Dr. Chamberland's filter will be of greater practical interest. For the sterilisation of liquids a biscuit tube is employed. Placed in a flask where vacuum is produced, the liquid is drawn through the biscuit or porcelain. This constitutes so fine a filter that even the minutest microbes are unable to pass. With a much larger ube fixed to an ordinary water-pipe, the water under usual pressure will filter through slowly; but by placing several biscuit tubes side by side, a sufficient quantity of water can be obtained for domestic purposes, in spite of the slowness of the process. A filter thus contrived and in working order is exhibited; and experiments made with one of the smallest known microbes, that of chicken cholera, prove that it cannot pass through the biscuit. The cleanliness of this filter is easily maintained, as the biscuit tube can be taken off, cleaned with a brush, or, better still, placed for a little while in the fire. The fourth side of the table is devoted to microscopical instruments. There are photographs all round of microbes, and close at hand a graphic sketch of M. Pasteur's kennels for the dogs, rabbits, &c., used in his researches. M. Houdard's apparatus for the prevention of the second fermentation of wine by heating to 145° F., and the appliances for the prevention of silkworm disease, both based on M. Pasteur's principles, are also close at hand.

Facing this centre of attraction, and forming part of the exhibits of the town of Paris, the chemist will find subjects of interest in the specimens from the Montsouris Observatory and the Paris Municipal Laboratory. The new apparatus which M. A. Dupré has brought into use for the analysis of food are shown, and some ingenious pipettes, but there are also many things that offer no novel feature.

Passing these two scientific collections, we at once enter upon the all-important question of water-supply and drainage. An inner chamber is entirely devoted to models bearing on these questions, and a great portion of the surrounding wall space is covered with drawings on the same subject. Official mortality statistics are given, with innumerable charts, &c., on the prevalence of typhoid fever, and maps of the districts most affected; so that we have side by side both cause and effect. In this the exhibits relating to water-supply are far more satisfactory than those concerning the drainage of Paris. It will be seen that Paris has two water-supplies, one for domestic purposes, and the other for watering the streets and industrial use. This necessitates the creation of two different systems of canalisation. The waters of the Seine, the Ourcq, and the Marne should only be used for watering purposes; but unfortunately this is not always the case. The pure waters of the Vannes and the Dhuis are sometimes insufficient for the domestic requirements of the capital. Maps, plans, drawings, and lengthy reports will be found affording the fullest information on all these points, and M. Couche, the chief engineer, may be warmly congratulated on the pains he has taken to make these matters clear and to give the fullest details in a terse and most intelligible manner. The newest features of this exhibit are the photographs and aquarel drawing of the water works at Ivry. They were completed last year, and can raise 84,000 cubic metres of water to a height of sixty-three metres in twenty-four hours. This great work was accomplished at the cost of £80,800. The new reservoir at Villejuif, constructed to receive this water, will cost £55,000, and when it is finished will supply a very powerful and much-needed flush for the Paris sewers. Indeed, these great works were undertaken with the view of assisting the projects of water drainage so warmly advocated by the partisans of English systems in Paris. But immediately opposite we find the whole scheme challenged by the presence of the apparatus employed by the town for carrying out M. Berlier's system of pneumatic drainage. The Municipal Council has sanctioned the application of this system to the richest and most fashionable district of Paris; it certainly constitutes the most novel and interesting feature of the Paris exhibits. Whatever may be said for or against it, and we have not space to enter upon this controversy at the present moment, it is the one new feature; and, considering the large scale on which it has been applied, the very weighty scientific and popular support it has received, the Berlier system has become a practical as well as a theoretical question.

The opposing theory is of less interest to Englishmen, for it is simply an attempt to impose on a different people and under different conditions an almost servile imitation of our English method of water drainage. A map shows that thirty-eight houses, barracks, or public establishments in Paris are now entirely drained into the sewer. A model and many plans and drawings of these buildings are given, but we must confess that most of them are unsatisfactory. The ventilation of the soil pipes is very imperfectly indicated: we failed to detect any provision for the inlet of air; and, though syphons are used, they are apparently not ventilated, and some seem so placed as to incur at least a slight danger of syphonage. A project for some villas in the Commune de Bondy, by M. Masson, is far in advance of anything that has actually been done; but unfortunately this is only a project. In this case the manholes with open channels and air inlets, as suggested by Sir Robert Rawlinson, are provided; and thus we find the best, instead of the worst, features of English drainage reproduced. But houses such as that of the rue Albouy, the house inhabited by the celebrated author Francisque Sarcey, in the rue Douai, and other specimens of what is known as the official installation of the *tout à l'égout*, only repeat the very defects which it is the object of such institutions as the Health Exhibition to prevent.

In Paris there is little or no water within the houses available for the purpose of flushing the soil pipes. Hence the law insists that these must be at least eight inches in diameter and vertical. Taking these facts into consideration, the celebrated firm of Rogier and Mothes, who manufacture from 30,000 to 40,000 closets per annum, may be congratulated on having made the best of bad circumstances. Where there is not an abundant flush of water the syphon trap can only be a source of danger. Messrs. Rogier and Mothes have, therefore, an iron enameled valve with a counter-weight in one piece. This is adroitly balanced, the pivot resting on a glass socket. The weight presses the valve tightly against the indiarubber flange that goes round the bottom of the closet pan. This is nicely adjusted so as to prevent the sewer gas passing through. Also the valve, holding a small quantity of water, forms a slight water seal, though the indiarubber is in this case the best protection. Yielding to weight, the valve opens automatically, and is so shaped that this action throws its contents down the soil pipe. At the bottom of the soil pipe, and sealing the opening into the cesspool another and larger automatic valve of the same description is placed. Indeed, as these valves cannot get out of order, any number of them may be used and placed at short intervals one from the other. Provision for the inlet and outlet ventilation of the soil pipes is also made, and this system of trapping is applied equally to waste-water pipes and the mouths of sewers. In the latter case the counter weight being much greater, a large volume of water accumulates before the valve opens, and thus an automatic and sudden flush is produced. The solids on the valve are

Digitized by Google

thrown well forward, a fact we have tested with heavy pieces of wet sponge, clay, &c. These closets, combined with the Berlier system, would enable the Paris authorities to drain the town without increasing to any large extent the water-supply. For countries where water is scarce, or the levels unfavourable, the Berlier system and Rogier and Mothes' closets offer a way out of the difficulty which merits the careful attention of the sanitary authorities. In the closets there is nothing to break; the action is automatic, and the same may be said of the apparatus for the pneumatic drainage. The successful working of such a combination would in no wise depend on care and cleanliness of the inhabitants, and is therefore especially suitable to populations who are ignorant of sanitary matters and have not been taught how to cope with sewer gas. In this latter respect, even the most prominent authorities of Paris have made a grave mistake, and a great educational work must still be accomplished before the French householder has learnt how to protect his dwelling from the foul emanations of soil pipe, sewer, and cesspool.

FOOD ADULTERATION AND ANALYSIS.

In a paper read at the Conference on this subject on the 14th inst., Dr. JAMES BELL remarked that the practice of adulteration is by no means of modern date, but has existed, more or less, from time immemorial. There is evidence that it was practised by the Greeks and Romans, and it has probably been co-existent with the development of commerce. The earliest enactments in this country in reference to food appear to have had a much wider scope than those of recent years, for they embraced the quality as well as the genuineness of the article, and dealers in foods or drinks which, from whatever cause, were considered as unwholesome were fined once or oftener, and then, if found incorrigible, were condemned to bodily punishment. With the exception of one or two Acts relating to the adulteration of bread, all the legislation upon articles of food from the time of George I. to the year 1860 had reference to the protection of the revenue, and therefore only indirectly guarded the health or pocket of the consumer. "In the year 1851 there was considerable agitation amongst planters and others interested in the production and sale of coffee, in consequence of the falling off in the consumption of that article caused by its wholesale admixture, as permitted by Treasury minute, with chicory. Petitions were presented to both Houses of Parliament on the subject, and it was perhaps the general attention directed at that time to this matter which induced the proprietors of THE LANCET to perform a public service of the highest value. In 1851 and several following years, at their own expense, they instituted an extensive inquiry into the character of the food, drink, and drugs sold in London, and engaged chemical and microscopical analysts for that purpose. The results showed that adulteration prevailed to an alarming extent, and that in many cases the adulterants were of a nature highly injurious to health. The Editor of THE LANCET showed his confidence in the analysts employed by publishing in that journal the results of the analyses, whether favourable or otherwise, together with the name and address of the vendor. The increased public attention thus caused, resulted in an inquiry by a Select Committee of the House of Commons in 1855, which reported that adulteration of food, drink, and drugs was very prevalent and that some of the adulterants used were of a poisonous nature. Following upon that report, and as a consequence thereof, the first general Act in this country was passed in the year 1860. This Act may have exercised to some extent a deterrent effect, but beyond this the practical outcome of it was but small, for the appointment of analysts was permissive, and the obtaining of samples for analysis was left to private purchasers. Another Act was passed in 1872, extending the right of appointing analysts to boroughs having separate police establishments, but still left such arrangements optional. A most important provision, however, was made for the purchase of samples by local officials, and the right was given to private purchasers to have samples analysed on payment of a small fee." The adoption of the Acts of 1860 and 1872 was by no means general, but was principally confined to London and the large towns; and even where adopted, the action taken was often of a very restricted character. The prosecutions which ensued, however, were sufficiently numerous to cause a general outcry from tradesmen about alleged miscarriages of justice; and in answer to petitions from most of the large towns, the Government decided to appoint another Select Committee of the House of Commons to inquire into the working of these Acts. This Committee recommended that the Acts of 1860 and 1872 should be repealed, and that a new, extended, and compulsory Act should be substituted for them. The chief amendments suggested were the inclusion of the fraudulent abstraction of an important property of any commodity, such as the removal of cream from milk, as a punishable offence; the examination of tea on importation; better regulations for obtaining samples, and for securing the appointment of qualified food analysts. To meet an important want provision was also made for obtaining an independent analysis in case of dispute. Upon the lines indicated in this report was framed the Bill which passed into law as the Sale of Food and Drugs Act, 1875, and which is the Act now in force, though amended in some respects by the Sale of Food and Drugs Amendment Act, 1879. It is much to be regretted that an evident unwillingness has been found on the part of some local authorities to bring these Adulteration Acts into operation. The Acts are practically a dead letter in some districts, even where nominally complied with, owing to the small number of samples purchased, or the conditions under which the purchases are made. In the twelfth report of the Local Government Board it is stated that in some cases "scarcely any attempt is made to conceal the official character of the buyers, or the purpose for which they are buying"; and the Board add, what must be perfectly obvious, "that unless the samples obtained by the inspector are of the quality ordinarily sold to the public, the object of the purchase is frustrated." In some districts the local authorities have been much discouraged by the small fines imposed by the magistrates, even when the offence has been committed more than once. There can be little inducement for them to carry out these Acts energetically when they find that after going to all the expense and trouble of the purchase and analysis of samples, and taking the necessary legal proceedings against a fraudulent tradesman, the heinousness of his offence is assessed by the magistrates at such a trifling sum as cannot be held to be a deterrent penalty, but one readily covered by the illegitimate profits of a few days. The tendency in recent years has been to place increased discretionary power in the hands of magistrates. For many years prior to 1879, their discretion in matters of fines in revenue cases was limited to reducing penalties to not less than one-fourth of the amount named in the Act. By the Summary Jurisdiction Act of 1879, however, they were given full discretionary power in first offences, but the former restriction remains in force for second and subsequent offences. Some such regulation may be found desirable under the Sale of Food and Drugs Acts, especially in cases where the vendor is the actual adulterator.

THE OLEATES AS THERAPEUTIC AGENTS.

THESE substances, which have lately come into evidence as therapeutic agents, formed the subject of a lecture which Dr. Shoemaker, of the Jefferson Medical College, Pennsylvania, U.S., lately delivered at the Westminster Hospital. After expressing the pleasure which he felt at addressing a body of English students for the first time, he proceeded to describe the imperfections of the oleates hitherto manufactured, which were not, he said, oleates at all, but merely solutions of oleic acid and the various bases, and in addition, owing to their oleic acid being derived from the "red oil" of the candle makers, they invariably contained a large proportion of oxyoleic acid and various other compounds, all possessed of an irritating action on the integument. He alluded to the first descriptions of the oleates by Chevreul, and later, 1872, their more definite classification

Digitized by Google

by Attfield and Marshall, and lastly, their true chemical combination as described by Dr. Shoemaker himself before the Medical Society of the State of Pennsylvania in 1879. Dr. Shoemaker claimed to have overcome the disadvantages attached to the employment of the older oleates, not only by having obtained definite chemical compounds instead of the unstable, unreliable solutions of oleates hitherto sold as such, but also that by drawing his oleic acid from other sources he has been enabled to produce it chemically pure and in a condition favourable to the formation of definite oleic salts with any given metal. Dr. Shoemaker insisted on the impropriety of employing any of the various petroleum products, vaseline, &c., as a basis for ointments, either of oleates or not, the animal fats having much more affinity for animal tissues than the former, and penetrating the epidermis and glands much more easily and completely. This he had established by a series of experiments extending over many years, both in the physiological laboratory on the lower animals and clinically in the wards, where one set of cases were treated with the metal or alkaloid in a petroleum basis, and a second group where lard was the vehicle. The results went to show that absorption took place much more rapidly and effectually in the latter set of cases than in the former. He remarked incidentally that the alkaloidal oleates were exclusively local in their action, no trace of them being obtainable in the secretions or excretions, although large quantities were used. For instance, the oleate of quinine, which in the hands of certain practitioners is said to possess a controlling influence over malarial fevers, has proved inert in the many cases which have been treated by its means by Dr. Shoemaker, nor was there any evidence of its having been absorbed. Veratria, similarly used, demonstrated even more markedly this difference. The lecturer next considered the individual oleates of the metals, the first being the oleate of aluminium; this is prepared by treating the sulphate of aluminium with sodium oleate, the result being a powder which, combined with a fatty substance, forms an ointment of service in muco-purulent discharges from the cutaneous surface, as, for example, in intertrigo occurring round the breasts and in the inguinal regions in eczema, and as a dressing for burns. It may be used in the proportion of from five to thirty grains to the ounce of lard. The arsenicum oleate, a reddish-brown waxy substance, is a preparation which, rubbed down with lard in from five to sixty grains to the ounce, according to the effect desired, forms a most important alterative and escharotic, of use in the treatment of epithelioma, ulcerating lupus, and in old chronic ulcers. Bismuth oleate, a pearly unctuous material, is a valuable emollient application in the various forms of rosacea, acne, sycosis, &c. Cadmium oleate, a yellowish-white mass, combined with lard in the proportion of from five to fifteen grains to the ounce, has a marked astringent action bordering on an escharotic, and has been extensively employed in the treatment of glandular enlargements and thickening of the integument. Copper oleate, a beautiful green substance, mixed with lard in from ten to sixty grains to the ounce, yields an elegant preparation, which is especially effective in ringworm, also in favus and tinea versicolor, or chloasma. The oleate by itself, melted and spread on muslin or leather, is of great service in thickened conditions of the integument, as corns, warts, and bunions. The oleate of iron is a reddish-brown mass, readily soluble in the fats, and has a decidedly styptic action, and may be used with benefit in arsenical sores. Lead oleate, similar in appearance to the cadmium oleate, when mixed with equal parts of lard produces an elegant ointment, which is preferable in its action to the litharge ointment, and has been much employed with satisfactory results in the various forms of eczema. Mercuric oleate made into an ointment with lard is useful as a discutient to inflammatory exudations, in thickened conditions of the integument, such as corns and warts, in pigmentary deposits, and parasitic affections. The mercurous oleate is a new preparation, which I have quite recently described for the first time, and may be used for the same class of cases where more decided effect is required. It is one and a half times as strong as the preceding, and it is the oleate which should be used in the inunction treatment of syphilis. Nickel oleate is a greenish waxy mass, which Dr. Shoemaker has employed in an ointment containing from five to fifteen grains to the ounce, as an application to hard, horny granulating surfaces. It resembles cadmium oleate in its astringent and somewhat escharotic effects. Silver oleate is a brownish pulverulent substance, and in the form of an ointment is valuable applied to ulcers, especially bedsores, in pruritus, erysipelas, and the old indurated ulcers met with on the extremities. The last of the series, the zinc oleate, is a white, pearly, impalpable powder, and is the most important of all the oleates. When diluted with an emollient powder it forms an excellent toilet powder for the face, particularly in seborrhœa oleosas, or "shiny face," and in intertrigo, and as an ointment it is most valuable in acute eczema, hyperidrosis, and bromidrosis. Dr. Murrell has used this preparation extensively, and has reported very satisfactory results from its employment.

THE NEW INFIRMARY AT FULHAM.

THIS building, situated near Hammersmith Station, and opened by Sir Charles Dilke on the 26th ult., has been erected for the accommodation of 446 sick poor, with an ample nursing staff, and is perhaps the most complete establishment of its kind consistent with the fact that it has been erected at a much less cost than similar recently erected establishments, although containing every requisite of a good hospital. The contract for the whole of the infirmary buildings, without machinery or fittings, was let in 1882 for £40,700. To this sum has been added further contracts for heating apparatus, engines, boilers, hot-water supply, laundry machinery, &c. These, with the original contract for buildings, and certain additional and extra works, also fittings and fixtures throughout, bring up the total cost of the institution (without furniture) to £51,422. The infirmary proper, with all its sanitary appliances, machinery, gas and water-supply, fittings and fixtures, has thus cost but £116 per bed. The ground plan comprises a central block, in which are placed the whole of the official and administrative departments; on the right hand side of the central block are placed two main blocks or pavilions for males, and one subsidiary one for special cases; and on the left two main blocks for females, and a subsidiary one for special cases. Between the two wards on each side are placed the receiving-rooms for patients. The main blocks are three storeys in height, and consist of wards ninety-six feet long and twenty-four feet wide, containing thirty-two beds each. Special attention has been paid to the ventilation, heating, and lighting of the buildings. Water for the use of the establishment is supplied at high pressure to all parts, and there are reserve tanks in the tower to contain a supply during any temporary stoppage through repairs to mains or otherwise. Fire mains are carried through every part of the building, and exits have been provided on each floor for patients in case of need. Every possible attention has been given to the sanitary appliances and drainage. All the lavatories, &c., are lined with white glazed bricks or tiles. No pipes are directly connected with the drains, nor can any effluvium enter the building. The drains have a good fall, and all the man-holes are ventilated. The guardians of the Fulham Union are to be congratulated on the acquisition of such an infirmary for the reception of their sick poor.

THE HIGHLANDS OF BRAZIL AS A HEALTH RESORT.

WE have received some notes on this subject from Mr. Arthur E. Jones, a gentleman whose complete recovery from indubitable phthisis after a residence in these mountains is vouched for by Dr. W. H. Walshe. On the east coast of South America from lat. 22° south to 26° a range of mountains runs parallel to the coast line and forms the boundary of the highlands of the provinces of Rio de Janeiro and S. Paulo. These provinces consist for the most part of table lands of 2000 to 3000 feet elevation, sloping gradually towards the interior and having a precipitous edge next the coast, and it is the climate of the region just within this edge that is specially eulogised by our correspondent. The towns in this district, being almost on the tropic of Capricorn, at an elevation varying between 2300 ft. and 2900 ft. above sea-level, have the sunshine of the tropics and the mildness and freshness of the temperate zone. The annual rainfall is about fifty inches, but since as much as an inch of rain some-

Digitized by Google

times falls in an hour, this fact must not be supposed to indicate a wet climate. At S. Paulo during 1875, rain fell on twenty days in the morning and afternoon, on eleven days in the morning only, and on fifty-nine days in the afternoon only. There is no winter as it is understood in England, but there is a season of six or eight weeks like an English May or September, when a fire is pleasant in the evening, and when there is occasional frost in the early morning in exposed situations. A most remarkable feature of the climate is the steadiness of the atmospheric pressure, the variations of the barometer being almost *nil*. The range during one whole year was only 0·7 in., rarely exceeding one-third of an inch during any one month. During 1875 the number of days on which the sun shone for the whole or greater part of the day was 215, distributed as follows:—January, 17 days; February, 14; March, 17; April, 21; May, 23; June, 22; July, 23; August, 24; September, 18; October, 22; November, 21; December, 23. During the year the maximum only once rose as high as 90° F. in the shade, twice to 88°, five times to 87°, twice to 86°, eighty-nine times it ranged from 81° to 85°, two hundred and six times from 70° to 80°, fifty times from 60° to 69°, and ten times from 52° to 59°. Nova Friburgo is the place most recommended as a resort for invalids. It contains a hydropathic establishment, conducted with much success by an Italian; and several Brazilian and German hotels, at which the cost of living amounts to about 9*s*. to 10*s*. 6*d*. a day.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham (*Urban*).—This large borough enjoys special advantages in connexion with elevation of site, undulation of surface, porosity of soil, &c., and, having regard to its population of nearly 415,000 persons, it does not stand badly as to general mortality when compared with other large towns and cities. Last year the death-rate per 1000 was 21·0. The vaccination statistics show very different results according to the unions in which the various parts of the borough are situated. In the Birmingham and King's Norton Unions the work is well done, but this is not so in the Aston Union, and Dr. Alfred Hill points out that while in Edgbaston, in the King's Norton Union, the percentage of children who live to the age of three months and remain unvaccinated is only 2·2, in Aston as many as 8·1, or nearly four times the number, evade the law in this respect. In this connexion we find that small-pox was very prevalent during the third quarter of 1883, and that the prevalence was maintained during the present year. Last year 1090 persons were treated in the borough hospital; and having regard to the interest now taken as to the possible distribution of small-pox from hospitals as centres, we note with some surprise that whereas a map is given showing the distribution of such diseases as measles, scarlet fever, and typhoid in the various parts of the borough, no such information is forthcoming as to small-pox. Scarlet fever was also very prevalent in 1883, this disease having caused 326 deaths. During the year a new isolation hospital intended only for the reception of cases of fever was opened, the pavilions already erected being a first instalment of a more complete establishment. As many as 412 deaths from diarrhœa took place, some 90 per cent. of these occurring in children under five years of age. Dr. Hill is of opinion that the great sacrifice of infant life from this cause during the hotter seasons of the year, though doubtless dependent on a number of causes, is in Birmingham at least largely due to the ignorance of the vast majority of mothers as to the proper mode of feeding and rearing their offspring. Dr. Hill's report is, as usual, a very comprehensive summary of a large number of subjects relating in various ways to the health of the borough under his supervision.

Hartismere (*Rural*).—Steady progress is being made in this district. The death-rate for 1883 was only 14·2 per 1000, and the death-rate under one year of age was as low as 9·5 per cent. of the registered births. Much has been done towards improving the water-supplies, and Dr. Barnes expresses the opinion that the sanitary state of the district is better than in any former year. There were eight outbreaks of diphtheria, but only one death occurred. Three of the outbreaks were in Mellis, a small village principally composed of houses scattered round a large undrained green, consisting of stiff wet clay. The outbreaks appeared to be quite independent of each other, and, as in former years, the occurrence of diphtheria in this place cannot be very satisfactorily accounted for.

Middlesex and Herts Combination.—Dr. Saunders prefaces his reports on the several sanitary areas within his combined district by a general report to all the authorities, and he is able to point out that during the past decade so large an increase in sanitary work has been carried out, and so much increased interest has been created in the matter of public health, as to augur well for future progress in the matter. Turning to details, we find him once more exhorting the Barnet urban authority to provide for the adequate cleansing of their sewers, either by requiring proper means of flushing to the waterclosets, or, if this is not done, by some special scheme for sewer flushing. Our opinion is that no watercloset should be tolerated that has not proper flushing apparatus, and this provision should, wherever possible, be insisted on. A somewhat similar want is felt in East Barnet. The undrained state of Hemel Hempstead is adverted to, and it is distinctly stated that to this cause are due the recurring outbreaks of enteric fever. The inhabitants themselves seem mainly responsible in this matter, being opposed to the expenditure of money. The need for hospital provision, as for example at Hemel Hempstead, is pointed out, and at Tring it is explained that by the use of the excellent hospital at Albury, belonging to the Berkhampstead rural authority, the spread of infection has been effectually stayed.

Milton-next-Sittingbourne (*Rural*).—This rural sanitary district, according to the census report, has an area of 28,350 acres, or forty-four square miles, and comprises sixteen parishes. The population in 1881 was 11,195, and Dr. Sutton, in his report for 1883, estimates the population in that year to be but 11,344, and only 149 more than it was at the time of the census; the method adopted for the estimate is not stated. The birth-rate during the year was stated to be 35 per 1000, decidedly high for a rural district; while the 175 deaths gave a rate of only 15·1, which is over-stated if the population be under-estimated. The births being 387, it is added that "the deaths under one year were 49, being to registered births under 8 per cent." Presuming that there is no misprint in the report, the proportion of deaths under one year to births was 12·7, instead of under 8, per cent., and this proportion is exceedingly high for a rural district. In other respects the report is a favourable one, the death-rate from the principal zymotic diseases not exceeding 1·5 per 1000, and being mainly due to ten deaths from whooping-cough. Dr. Sutton is able to report that the local estimation of the value of the infectious diseases hospital is increasing, and the prejudice against its use is disappearing. This augurs well for the future sanitary welfare of the district. The report of the inspector shows that much useful work was done in his department during the year.

Hackney.—Dr. Tripe reports that sanitary work has been more actively carried out in his district during 1883 than in any year since 1866, the causes being, first, the stimulus to work given by the outbreak of cholera in Egypt, and secondly, the inspections which were made in connexion with the question of work under the Artisans and Labourers' Dwellings Acts. A description follows of some of the worst property in the district; and as regards some of the houses, it is stated that unless they are pulled down very shortly compulsory action will have to be taken. Special reference is made to the danger resulting from brick drains under houses. These old culverts almost invariably contain a considerable deposit of filth, and the last place where they ought to be tolerated is beneath dwelling-houses. As regards what are generally known as tenement houses, it appears that for many years past a large amount of inspection and improvement has been carried out, and that the regulations hitherto in force require a larger amount of cubic space per head than is the case in any other metropolitan district. New regulations have, however, now been drawn up and submitted to the President of the Local Government Board, with a view of bringing them into conformity with the more recent statutes relating to the subject. The general improvements effected in the district include a large amount of disconnexion of sink and overflow

Digitized by Google

effect improved water services to closets and otherwise, the provision of cisterns instead of butts, the substitution of efficient traps for the imperfect bell-traps, and the cleansing of cow-sheds and slaughter-houses, &c. All such work, when attended to in its various details, removes from amongst the people constant sources of nuisance and ill-health, and must hence be regarded as amongst the most important that can be carried out. The death-rate for Hackney during the year was at the rate of 17·6 per 1000, as opposed to 20·4 in London generally. Some of the mortality was due to small-pox, apart from cases of strangers brought to Homerton Hospital, and Dr. Tripe gives some interesting account of the outbreak and of the protective power of vaccination. The number of houses and articles disinfected during the year was very considerable.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5507 births and 3726 deaths were registered during the week ending the 12th inst. The annual death-rate in these towns, which had been so low as 18·7, 19·2, and 19·5 per 1000 in the three preceding weeks, further rose last week to 22·2. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·8 per 1000, against 20·9 and 21·5 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 11·1 in Plymouth, 12·5 in Derby, 13·3 in Bristol, and 13·9 in Brighton. The rates in the other towns ranged upwards to 24·7 in Birkenhead, 24·9 in Liverpool, 25·2 in Nottingham, and 25·9 in Halifax. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 495, 514, and 572 in the three previous weeks, further rose to 876 last week, the increase being mainly due to the greater mortality from diarrhœa; they included 495 from diarrhœa, 103 from whooping-cough, 102 from measles, 71 from scarlet fever, 51 from "fever" (principally enteric), 32 from small-pox, and 22 from diphtheria. No death from any of these diseases was registered last week in Derby, while they caused the highest death-rates in Wolverhampton, London, and Nottingham. The greatest mortality from diarrhœa occurred last week in Nottingham, London, Leicester, Bolton, Leeds, and Preston; from whooping-cough in Sunderland and Leicester; from measles in Halifax and Wolverhampton; and from scarlet fever in Cardiff and Sheffield. Of the 22 deaths from diphtheria in the twenty-eight towns 15 occurred in London and 2 in Brighton. Small-pox caused 21 deaths in Registration London, exclusive of 15 London cases registered in the metropolitan asylum hospitals situated outside Registration London; also 6 in Liverpool, 2 in Sunderland, 1 in Sheffield, 1 in Hull, and 1 in Cardiff. The number of small-pox patients in the metropolitan asylum hospitals, situated in and around London, which had been 1290 and 1368 on the two preceding Saturdays, declined to 1249 at the end of last week; the number of new cases admitted to these hospitals declined to 179 last week, from 354, 260, and 266 in the three preceding weeks. The Highgate Small-pox Hospital contained 79 patients on Saturday last, showing a further decline from numbers on preceding Saturdays; 18 new cases were admitted last week, against 22 and 20 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 218 and 231 in the two previous weeks, declined to 206 last week, but exceeded the corrected average by 10. The causes of 101, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Newcastle-on-Tyne, and Plymouth. The largest proportions of uncertified deaths were registered in Birkenhead, Manchester, Sheffield, and Cardiff.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 20·6 and 21·8 per 1000 in the two preceding weeks, was 21·0 in the week ending the 12th inst., and was 1·2 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·5 and 16·4 in Leith and Edinburgh to 29·4 in Paisley and 33·6 in Perth. The 507 deaths in the eight towns included 32 which were referred to diarrhœa, 23 to whooping-cough, 10 to scarlet fever, 10 to measles, 9 to diphtheria, 3 to "fever," and not one to small-pox; in all 87 deaths resulted from these principal zymotic diseases, against 86 and 78 in the two preceding weeks. These 87 deaths were equal to an annual rate of 3·6 per 1000, which was 1·6 below the mean rate from the same diseases in the twenty-eight English towns. The 32 deaths attributed to diarrhœal diseases showed a considerable increase upon recent weekly numbers, and exceeded by 11 the number in the corresponding week of last year; they included 10 in Glasgow, 6 in Dundee, and 5 both in Leith and in Paisley. Diarrhœal fatality in the Scotch towns last week was, however, less than half that recorded in the English towns, after correction for difference of population. The 23 fatal cases of whooping-cough in the Scotch towns showed a marked decline from recent weekly numbers, and included 11 in Glasgow, 5 in Edinburgh, and 4 in Aberdeen. Nine of the 10 deaths from scarlet fever, showing a considerable increase upon the numbers in recent weeks, occurred in Glasgow. The 10 fatal cases of measles corresponded with the number in the previous week, and included 7 in Glasgow. The deaths referred to diphtheria, which had been 7 and 10 in the two previous weeks, were 9 last week, of which 2 occurred in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The 3 deaths from "fever" showed a decline from the numbers in recent weeks. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 85 and 83 in the two previous weeks, declined to 54 last week, and and were 27 below the number returned in the corresponding week of last year. The causes of 80, or nearly 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 27·1, 28·2, and 21·0 per 1000 in the three preceding weeks, was 22·3 in the week ending the 12th inst. During the thirteen weeks of last quarter the death-rate in the city averaged 26·5 per 1000, whereas the rate during the same period did not exceed 19·9 in London and 21·6 in Edinburgh. The 159 deaths in Dublin last week showed an increase of 9 upon the number in the previous week, and included 13 that were referred to the principal zymotic diseases, against 14 and 18 in the two preceding weeks; 5 resulted from "fever" (typhus, enteric, or simple), 4 from whooping-cough, 3 from scarlet fever, 1 from diphtheria, and not one either from small-pox, measles, or diarrhœa. These 13 deaths were equal to an annual rate of 1·9 per 1000, the rate from the same diseases being 6·8 in London and 2·5 in Edinburgh. The deaths referred to "fever" in Dublin, which had been 7, 5, and 2 in the three previous weeks, were 5 last week. The 3 fatal cases of scarlet fever showed a decline of 7 from the number in the previous week, while those of whooping-cough showed an increase. Nine inquest cases were registered, and six deaths were referred to violence; 54 deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed an increase upon the numbers returned in the previous week. The causes of 16, or rather more than 10 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General William Stewart, M.D., is granted retired pay, with the honorary rank of Surgeon-General. Brigade Surgeon William Henry Corbett, M.D., to be Deputy Surgeon-General, vice W. G. N. Manley, V.C., granted retired pay. Brigade Surgeon John Henderson Whittaker is granted retired pay, with the honorary rank of Deputy Surgeon-General. Surgeon-Major Samuel Stacy Skipton, M.D., to be Brigade Surgeon, vice W. H. Corbett, M.D. Deputy Surgeon-General T. W. Fox has been appointed to act as Principal Medical Officer of the British Army of Occupation in Egypt, vice Surgeon-General J. Irvine, granted special leave of absence to England till September next.

INDIA OFFICE.—Surgeon-Major Henry William Graham, of the Bengal Army, has retired. Surgeon-Major Francis Ronayne O'Kearney, M.D., of the Bombay Army, has been transferred to the retired list.

ADMIRALTY.—Staff Surgeon Donald MacIver, M.D., has

Digitized by Google

been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet. Surgeon William S. Lightfoot has been appointed to the *Duke of Wellington*.

ARTILLERY VOLUNTEERS.—2nd Devonshire: Frederick Everard Roe, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS. — 1st Volunteer Battalion (the Leicestershire Regiment): Surgeon and Honorary Surgeon-Major Edward Ranson Denton resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.—3rd Forfar (Dundee Highland): Charles Stewart Young, Gent., to be Acting Surgeon.

Brigade Surgeon Elkington, M.D., Grenadier Guards, Staff Surgeon-Major Hamilton, M.D., and Surgeon Pocklington, M.D., 3rd Surrey R.V., are again in charge of the field hospital at the Wimbledon meeting.

Correspondence.

"Audi alteram partem."

CHOLERA, ITS ETIOLOGY AND TREATMENT.

To the Editor of THE LANCET.

SIR,—I have been anxious for some little time to ask you to allow me to recommend in your pages a treatment of cholera which, in India in 1865, when Surgeon-Major of the 72nd Highlanders, I found, beyond all comparison, more successful than any other I had ever tried, during a rather extensive previous experience of the disease in Canada and the Crimea, as well as in India. I have been hitherto deterred from addressing you by the fact that, although I felt sure that two-thirds of the cases treated at the time I refer to recovered, I had no record of the fact, nor of the number of cases treated. Meeting, however, a few days ago Lieut.-General W. Payn, C.B. (very lately returned to England from the command of a division of the Madras Army), who was Colonel commanding the 72nd Highlanders at the time I speak of, at Poona, near Bombay, and who had taken great interest in the cholera cases which occurred in the regiment, he asked me whether I had published any statement of the treatment I had employed. I told him I had thought of writing to THE LANCET, but that, as above stated, I had no figures to give. He then told me that he had been so much struck with the comparatively small proportion of deaths from cholera in the regiment in Poona in 1865, that he had obtained, before the regiment embarked for England in October of that year, a return of the admissions and deaths from cholera in the 72nd and in the two other European infantry regiments stationed at Poona; that he was pretty sure that in the 72nd there were fifteen admissions and four or five deaths, a statement which quite corroborated my impression as to the proportion of recoveries, a very large proportion in true Asiatic cholera. General Payn believes he still possesses the return, and when he can lay his hand upon it he will let me have particulars.

I will now state what the treatment was. A dose of calomel, followed immediately by cold affusion, frequently applied. What led me to think of this treatment was this. At Mhow, Central India, in 1859, when some cases of cholera occurred in the 72nd I was advised, by the late Deputy Inspector-General of Hospitals, Dr. Archibald Stewart, to try the cold affusion, which, he said, had been used with success in Bengal by a medical officer, whose name I am sorry I do not remember. I did so, and certainly with some success, inasmuch as the cramps were much relieved by it, and reaction to some extent obtained. I am writing from memory, having no notes of these cases, but (whether it was because I did not repeat the baths sufficiently often or not I cannot tell) I think I had not much more ultimate success than I had obtained under other methods of treatment. A few years later it occurred to me that, as in cholera the secretions are arrested, if I could introduce into the system a dose of calomel, which is said to promote all the secretions, and could then induce a certain amount of reaction by the cold affusion, the calomel might do good, being, as it were, on the spot, ready to promote secretion.

When, then, cholera appeared in the regiment in 1865, I adopted this treatment. I usually began with ten grains of calomel, and if there was much vomiting, five grains more were given. The patient, even if in a state of complete collapse, was then stripped of all clothing, carried in the horizontal position to the bath-room, where he was laid on a bedstead without any bedding. Three or four large earthenware "chatties" of cold water, the coldest we could get, were then dashed over him. He was rubbed dry with towels as rapidly as possible and replaced in his bed. The patient almost invariably felt relief; the cramps were mitigated, and sometimes in cases of collapse the pulse could now be just felt. In about five minutes the bath was repeated as before, after which, even in the worst cases, the pulse could now generally be felt; the skin became warmer, and the patient would beg for another bath. With reaction, vomiting and purging gradually ceased. The cold affusion was used at least five or six times in each case, at intervals varying according to circumstances; and, as a rule, after each application of it the pulse grew stronger and all symptoms improved. Experience had taught me long before that all piling of bedclothes on a cholera patient, the application of heat, as by hot bottles, hot turpentine, &c., were almost loathed by him, and that the only thing he ever begged for, besides water to drink, was to have his limbs rubbed when he was tortured with cramps. In the intervals between the baths, the patient had merely a sheet thrown over him, with a thin blanket or coverlet; and if there were any lingering cramps, the parts affected were rubbed with the dry hand. Such was the treatment. I need hardly add that when all immediate danger was over, the patient always required the most careful and watchful treatment, not only for days, but for weeks. Sometimes diarrhœa would come on, or consecutive fever, rendering recovery very slow. One patient, after recovery from cholera, succumbed to mucous enteritis fourteen days after admission. Only one patient I failed to rally from collapse. He was a staff sergeant, who lived by himself in a small detached bungalow, and was found early one morning by a soldier lying on the floor of his bedroom in a state of extreme collapse. I could make no impression on this case; he was too far gone when I saw him.

I am, Sir, yours faithfully,

W. C. SEAMAN, M.D.,
Deputy Inspector-General of Hospitals.

Junior United Service Club, S.W., July 16th, 1884.

To the Editor of THE LANCET.

SIR,—It is nigh twelve months since you gave insertion to an article by me on cholera epidemic, wherein I expressed the view that cholera is a specific fever analogous and of a severity inferior to yellow fever; that the temperature is raised, and that the low indication is caused by the abstraction of heat by the surrounding media, the fevered body being incapable of preserving its temperature uniformly; that cholera is not caused by a fungus, as maintained by Klebs, De Bary, and Hallier, and now advocated by Koch, nor is it dependent on any peculiar fomentable condition of the underground moisture layer as propounded by Pettenkofer; and that it is contagious, and may be originated and propagated even when the water is good. Surgeon-Major Fitzgerald took exception to the statement that the water of any Indian village is good. If the Indus, where it is two-thirds of a mile wide, running five miles an hour, and averaging twelve feet, can be polluted for over two months, then the drinking water of Kotree in 1869 was bad. But I look upon the insinuation as absurd. A few authorities deny the contagion because they have witnessed attendants escape contagion. Well, if attendants did not escape contagion; any epidemic of a contagious disease would affect the entire population of a country. Dr. Cuningham and Sir J. Fayrer consider cholera a malarial or effluvial disease, and Sir J. Hunter deems the poison an entity which is capable of being nursed through diarrhœal cases, and stored up till the period for an epidemic arrives in the unhealthiness of the people. I trust no one believes that cholera or its contagium existed in the Ark as a specific thing; this being granted, it follows that cholera may under extraordinary and exceptional circumstances arise spontaneously. In the epidemic through which I passed I had many cases to which a trace of contagion communication could not be assigned, but the vast majority were otherwise. Spontaneous combustion is possible, yet in most instances of conflagra-

Digitized by Google

tion the originating and propagating cause is the kindled spark. No one thinks that other than insanitary conditions are inviting to cholera. The meteorological states which favour disease in plants and animals, and precipitate it in man, nurse cholera: heat, moisture, stillness, and free electricity have developed disease like a shadow passed, but for this purpose it is essential that the constitution of the plant or animal should be below par. Most thinkers concede that cholera observes a periodicity in its occurrence; whether incident to moral causes (like the commercial panics), to physical (like the floods), or celestial (like the sun-spots), has not been argued.

The statement which I made in my article in THE LANCET, July 28th, 1883, that cholera has a predilection, or seems to wear itself out amongst a people, is expressed in other words by Dr. Darwin—"that the effluvia or exhalations from one group of people may be poisonous to another group," and disease may break out among a people who come into contact with another, even though the latter have no positive manifestation of such." Dr. Blanc has contributed cases to THE LANCET where the temperature was raised in every stage. The regulators of metabolism are totally disarranged in the severer forms of fever; the nervous system is numbed; the excretory and genetic organs are, as it were, paralysed. Thus is it that stimulating frictions, shower baths, emetics, cholagogues, &c., do good by acting on the nervous controllers of metabolism. The cholera witnessed by Dr. Lucas in new-born children discards at a stroke the fungus theory. To show my faith in the proposition "that fungi or bacilli in cholera are mere indices of the disease and not the cause," I would swallow any amount of Prof. Koch's bacilli provided they are well washed in distilled water until the colour of the permanganate solution is slowly affected. "Wherever organic matter decays, fungi sit upon it and devour it" (Pasteur). The world was not made so imperfect as to leave us a prey to such a capricious, insidious, and treacherous enemy as Prof. Koch would describe the cholera bacillus to be.

I am, Sir, yours truly,

JOHN ROCHE, M.D.Q.U.I.,
Retired List, Indian Medical Service.

Mount Clarence, Kingstown, June, 1884.

P.S.—I failed to communicate cholera to hungry pariah dogs through cholera discharges, rotten eggs, carrion, and combinations covered with milk and chapatties.

RELATION BETWEEN THE SPLEEN AND THE THYROID.

To the Editor of THE LANCET.

SIR,—In reading your article in THE LANCET of May 17th, 1884, referring to Tauber's recent experiments on the splenic function and his deductions from those experiments, a clinical point has occurred to me as tending to strengthen very much the conclusion arrived at from experiment—viz., the absence of any physiological affinity between the spleen and thyroid gland.

In 1881 and 1882 I was in a district where goitre is endemic, and among upwards of 2000 cases of goitres of all kinds I find, from reference to my notes of recorded cases, not a single case of anæmia in a goitrous subject. This would be a very remarkable fact if there were really any such affinity as has been asserted between the spleen and the thyroid. Were this the case, we should with reason expect to find at least some degree of anæmia in cases of hypertrophied thyroid. In hypertrophied spleen there is, I think I may say invariably, some degree of anæmia or leucocythæmia, varying directly as the amount and duration of the splenic enlargement. The question at issue being the identity of function of the spleen and thyroid, it appears to me that the fact, which is indisputable, that similar changes in the two organs do not produce similar effects on the mass of the blood, affords conclusive proof that the physiological functions of the two organs are, as far at least as the blood is concerned, dissimilar. Again, splenic enlargement in this country is almost exclusively malarial; thyroid enlargement, on the other hand, owns no such cause. Further, constitutional treatment, which with certainty reduces an enlarged spleen, has not the slightest effect on the enlarged thyroid body. And lastly, inunction of biniodide of mercury ointment in enlarged thyroid never to my knowledge results in cancrum oris, while such a result in malarial splenic enlargement is by no means uncommon in my experience.

The function of the thyroid body remains imperfectly defined; but, whatever that function may be, it appears certain that it has no affinity with the spleen as a blood modifying organ.—Yours faithfully,

GEORGE S. A. RANKING, M.D. Cantab.

Punjab, June 8th, 1884.

"COVENT-GARDEN MARKET."

To the Editor of THE LANCET.

SIR,—As the responsible agent of the Duke of Bedford, I beg to state that your article on the subject of this market seems to have been written under a misapprehension of facts. Within the market quadrangle I unhesitatingly deny that there is any neglect of "ordinary cleansing and the prompt removal of offal." The whole of the market is regularly swept twice a day, and many of the gangways thrice or oftener. The contractor's men and carts are in constant attendance. A large sum is paid for the cleansing, but the work is exceptionally heavy, and is required to be well done. All the sanitary arrangements within the market are under the direct supervision of the estate surveyor, and the costly latrines erected a year or two ago are admitted to be the best of their kind in London. I am privileged to know many of the medical men in the neighbourhood, and I am not aware that the state of health among the salesmen and their servants is otherwise than satisfactory. Obviously a market that is limited in size, that at certain seasons is in use throughout almost the whole twenty-four hours, over which the traffic never ceases, and in which all the commodities sold give out refuse, presents peculiar difficulties in the way of management. There must inevitably be periods of apparent confusion and untidiness. These periods frequently occur, and the more frequently during such seasons as the present, when fruit and vegetables are continually arriving from the suburbs of London, the south of England, the Channel Islands, and the Continent. But no expense is spared to secure efficient control, and especially to have as prompt a clearance of all refuse as the business of the market will permit. For the proper cleansing of the streets leading to the market quadrangle the Strand District Board is wholly responsible, the traffic being regulated by the police. The public crowd their vehicles into these approaches, and by their continuous occupation hinder the contractor employed by the district board from efficiently doing his work. Added to this is the circumstance of shopkeepers blocking up the roadway with their merchandise, instead of keeping it within their shops. These are matters that are entirely under the control of the police. I quite concur in your remark that the cross traffic is an occasion of much inconvenience, but the police alone can deal with this difficulty. Although Covent-garden Market is private property, yet from its popularity and use it has acquired a quasi-public character, and therefore is open to criticism; but that criticism should be reasonable and truthful.

I am, Sir, your obedient servant,

Bedford Office, July 11th, 1884. JOHN D. BOURNE.

CHOLERA AND SANITATION ON THE RIVIERA.

(*From a Correspondent.*)

THE fact that cholera has spread from Toulon to Marseilles, and thence to Aix-en-Provence, Nîmes, Grenoble, &c., not to mention a number of outlying villages, Sollies, La Seyne, Collabrières, and the beautiful valley or gorge of Ollioules, must naturally suggest that, even if Paris and England escape the scourge, the Riviera, in any case, is in the greatest peril. Though cholera is so near at hand, the celebrated health resorts of this favoured district might have escaped had sanitary measures kept pace with the increase of population. The people in the south of France, however, are slow to move, and what little progress has been accomplished is mainly due to the pressure brought to bear by the numerous English residents. Hence the question of drainage, though earnestly discussed at Cannes,

Digitized by Google

Nice, Monaco, Mentone, and other health resorts, has remained in abeyance at Marseilles and Toulon, where comparatively few English reside. The result, however, in either case, is anything but satisfactory. The sanitary condition of the entire Riviera is such as to offer no security against cholera; and this is a most serious matter, both for the native population and the very large number of English who prolong their lives by wintering in the South.

The nearest health resort to the present centre of the cholera epidemic is the town of Hyères, which is only fifteen miles from Toulon. The sanitary condition of this town is truly deplorable; its death-rate is about 28 per 1000, which, considering the smallness of the population, is high even for the Riviera. Along the main street there is a ditch to which the complimentary name of sewer is given. It is some three feet deep, and simply covered over by the flagstones of the side-walk. The intervening space between the loose fitting stones supplies means of ventilation, but there is no protection against the effects of the sun, which acts directly upon the sewage below. In some places the fall is insufficient, and at one point the sewer had an inclination upwards. But a sudden death in a house opposite this defect alarmed the authorities, and the level has been rectified. This sewer receives the overflow of several cesspools and the slop-water of the neighbouring dwellings. None of the conduits are trapped, so that the foul air of the sewer rises into the houses. There are no proper means of flushing, and the sewage, freely exposed to the heat of the sun, rapidly ferments. Cesspools abound on all sides, and are for the most part built immediately under the houses.

The primitive system of drainage, if it may be so called, still prevalent in the old portions of the various towns on the Riviera, was less dangerous than the unscientific modern methods introduced for the special benefit of foreign visitors. The streets had no sewers, the houses no closets and no cesspools. What little water was used for washing purposes and the kitchen water was poured away into the gutter, which ran down the centre of the street to the river or the sea; and as every town was built on a hill-side, it quickly passed away. Whatever foulness there might be, was at least exposed to the purifying action of the open air, and not drawn up by untrapped pipes into the interior of the houses. With regard to the night soil, this was kept in small wooden barrels, and when two were filled they were placed on the back of a donkey or mule, taken up the hill-side, and used to manure orange, olive, or lemon trees. Thus what is known as the pail system was carried out to the great benefit of the surrounding agriculture. These buckets were nasty but not particularly dangerous, and from a sanitary point of view infinitely preferable to cesspool or badly constructed sewers with untrapped house-drains. This system, however, was only practicable when each householder had his plot of land to cultivate in the outskirts of the town; and for hotels, &c., houses with cesspools were built. Subsequently sewers were laid, at least in the more fashionable portions of the town. These sewers were made to receive only the surface water together with the kitchen and washing water; but, in innumerable cases, the rules are defied and the sewers are polluted by overflows from the cesspools. This is all the more dangerous as the sewers are much larger than those used in England; while, on the other hand, they are rarely and, in many cases, never flushed, except by storm water. The accumulation of deposits is the natural result; and the local engineers have so little faith in a self-cleansing sewer, that they invariably insist on the channels being large enough to admit the passage of a man, so that they may be occasionally cleaned by hand. Though English sewers receive everything, they are ventilated with some care, constantly flushed, and are comparatively so small that the rush of water is really effective in cleansing them.

Putting aside the few isolated villas standing in the centre of gardens, which have been drained under English supervision, the great majority of the higher class houses in all the towns of the Riviera are exposed to a twofold danger. First of all there is the cesspool, which has, it is true, its ventilating shaft carried to the roof of the house; but the soil pipe, being within the house, has a higher temperature, and is therefore a more active ventilator of the cesspool. This pipe is generally of iron, at least eight inches in diameter, and can never be kept clean. There may be a valve under the closet pan, but there is no syphon trap, and no effective means of excluding the effluvium from the cesspool, which is generally situated under the inhabited portion of the house. Secondly, all the waste water pipes communicate directly with the sewers, and, being untrapped, supply about the only means of ventilation existing. Thus the houses are impregnated with the effluvium from the cesspools brought up by the soil pipes and by the sewer gas drawn up through the waste water pipes. Under such circumstances the high death-rate of every Riviera health resort need not surprise anyone. But when we consider that at any moment the specific germs of cholera may be distributed throughout this defective system of drainage, the prospect may well awaken the keenest alarm. If the practice of isolation in cases of infectious diseases had become customary, we might feel less anxiety; but the principles that govern us in such matters are ignored. The disinfection of dejections from typhoid patients is rarely if ever attempted, while thorough fumigation after infectious fevers is in no wise enforced. There was not a single public disinfecting stove along the whole Riviera till a few months ago, when Dr. Albenois constructed the model of a portable stove at Marseilles, which however up till last December had never been used, and was only shown as a curiosity. If, therefore, one or two cases of cholera are imported into any of the Riviera health resorts, the sewers may be contaminated, and then there will be no safety for the inhabitants of the houses that drain into these badly constructed channels. Yet an epidemic would be the ruin of such towns, for their prosperity depends almost exclusively on the presence of foreign, especially English, visitors. Perhaps this prospect may serve to arouse the inhabitants to a truer sense of their real interests. They may finally learn that for health resorts good sanitation is more important and profitable than the plantations of avenues of palms, the construction of new boulevards, or the erection of theatres, casinos, clubs, and other attractions which, though they may amuse, cannot in themselves impart health, cure disease, or ward off epidemics.

LIVERPOOL.

(From our own Correspondent.)

THE CHOLERA.

THE prevalence of cholera in France recalls vividly the epidemic of 1866, and it is instructive to notice the difference in our past and present sanitary laws. Had the local authorities possessed in 1866 the same powers as they have now, they would have been enabled, humanly speaking, to have arrested the disease at the onset and to have saved many lives. The spread of the infection was caused by a wake being held on the body of one of the first victims of the disease in a crowded court in one of the poorest streets, and there was no law to prevent the wake nor to remove the corpse. At the present time the local authorities on each side of the Mersey, as well as in the river itself, are furnished with ample powers to prevent the pestilence from being brought ashore; but should this be frustrated, it can be at once isolated and checked. These powers, which were conferred by the Public Health Act, have since proved to be of the greatest value.

THE EPIDEMIC OF SMALL-POX.

Ample provision has been made for the accommodation of small-pox patients in temporary hospitals erected on the grounds near Parkfield House, which latter is for the resident staff. The site has been well chosen, and by a coincidence the epidemic began to subside as soon as the arrangements were completed. The epidemic has been useful in proving the necessity of a permanent hospital for infectious diseases, independently of that afforded by workhouses. Another lesson has been taught, which it is to be trusted will not be forgotten, and that is the importance of universal revaccination in adult life. Much might be done if all employers of large bodies of workmen insisted upon its performance before engaging any applicants. As it is, revaccination is seldom demanded except in times of epidemic, and then only by the better classes.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The annual meeting, under the presidency of Henry Rayner, M.D., will be held at the Royal College of Physicians, Pall Mall, on Wednesday, July 23rd, at 11 A.M. and 2 P.M.

Digitized by Google

IRELAND.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

AN election for a lecturer on Surgery in the Medical School of the College will take place on the 24th inst., and two of the candidates, Messrs. Corley and Hamilton, have had to resign the Vice-Presidency and the membership of the Council respectively, in order to qualify for the appointment. The President, in consequence of a requisition, has named the 21st inst. as the day to fill up these vacancies; and the candidates for Council consist of Messrs. Meldon, Nixon, and Story. For the Vice-Presidency there are two candidates, Dr. Cameron, medical officer of health for Dublin, and one of the professors of the School of Surgery; and Mr. Ormsby, surgeon to the Meath Hospital.

ROYAL UNIVERSITY OF IRELAND.

At a recent meeting of the Senate the following arrangements for 1885 were adopted. There are to be two matriculation examinations in each year, conducted at local centres, one in June for pass candidates only, and the second in October; the First University Examination is to be held twice yearly, while the examinations for A.B. and A.M., and the Second University Examination in Arts, and for the University studentships will take place in September. The medical examinations of the University are to be held twice in each year—viz., towards the end of April and in the month of October. Candidates failing to pass at either of these will be allowed to present themselves again at the succeeding examinations. There will be a Honours Examination in connexion with each of these medical examinations; and one first class exhibition and one second class exhibition out of the number already assigned to the several medical examinations respectively may be awarded at the one held in April, while the residue of such exhibitions may be awarded at the October examinations. At a meeting of the Senate held on the 7th inst., Dr. John F. Hodges was elected an examiner in Sanitary Science.

DISPENSARY MEDICAL OFFICERS IN IRELAND AND THE COMMISSION OF THE PEACE.

In consequence of a recent statement that the medical officers of dispensary districts in Ireland are ineligible to hold Her Majesty's Commission of the Peace in Ireland, considerable dissatisfaction has arisen, and a memorial has been framed for presentation to His Excellency Earl Spencer drawing attention to the matter.

PRECAUTIONS AGAINST CHOLERA.

Great precautions are being adopted in the Health Department of the Corporation of Dublin by Dr. Cameron, the energetic medical officer of health for that city, so as to be prepared in case the cholera should visit these shores. The inspectorial staff has been doubled, and faulty privies are being attacked vigorously. One hundred and forty-four waterclosets were put up last month in the tenement houses in place of the middens previously existing. These privies in connexion with tenement houses in Dublin have done much to pollute the soil and air of the city, and the substitution of waterclosets must be regarded as a very satisfactory arrangement.

The amalgamation scheme of uniting the private Medical Schools with that of the College of Surgeons was defeated at the Council by eight votes against six. The motion has been remodelled, and has been referred to the Education Committee to report on the feasibility of amalgamation.

The President of the Royal College of Surgeons in Ireland has left for London, to have an interview with Mr. Mundella in reference to the Medical Acts Amendment Bill.

Dublin, July 15th.

ROYAL COLLEGE OF PHYSICIANS.

AT the adjourned Comitia, held on Thursday last, the only important business transacted was the appointment of a Committee to draw up a list of recommendations to be submitted to the Local Government Board, and to be issued to the public for their guidance in the event of the appearance of Asiatic cholera in England.

MEDICAL NOTES IN PARLIAMENT.

The State of the Thames.

IN the House of Commons, on Friday, Sir W. Harcourt, replying to Dr. Cameron, said there was no doubt the river was in a very serious state in consequence of the sewage which was being poured into it. He had communicated with the Royal Commission which was now sitting, and also with the Metropolitan Board, and in his opinion immediate and urgent measures ought to be taken.

On Monday, in answer to Sir A. Lusk, Sir C. Dilke stated that all the sewage at the main outfall was now deodorised by the Metropolitan Board, but there were many sewers discharging into the upper part of the river without any purification. A scheme for dealing with this had been proposed by a joint sewerage board, but it was understood that the committee who were considering the Bill were going to throw it out. If so, they accepted a grave responsibility, and most serious difficulties would result. He was inquiring as to the effect upon the river of the abstraction of water by the water companies.

Vaccination Inspection.

In reply to Mr. Hopwood, Mr. Mundella read a letter he had received from Dr. Buchanan, stating that in only one instance had he ever met with any objection to his examining the arms of children in public and private elementary schools. His custom was to give a list of the unvaccinated children to the master of the school, and to ask him to call the attention of the parents to the fact that they were not protected against small-pox.

Cholera Hospitals.

Mr. Trevelyan stated to Colonel Nolan, on Tuesday, that there was no authority in Ireland which possessed a portable hospital that might be put at the disposal of any union where cholera broke out. The sanitary authorities at Dublin, Queenstown, and Londonderry had floating or other intercepting hospitals.

On Thursday, in reply to a further question, the right hon. gentleman stated that in the event of cholera reaching this country it would be the duty of local sanitary authorities to provide hospitals.

Cholera in India.

Mr. Cross, in reply to Dr. Cameron, agreed to present a copy of the correspondence between the Government of India and the Sanitary Commissioner of Madras as to the report of the latter, in which a cause was assigned for an outbreak of cholera. The Government view was that the sanitary officers should refrain from stating theories as to the propagation of cholera. In answer to Mr. O'Donnell, the hon. gentleman said the scarcity of salt had nothing to do with the cholera in India. The condition of the finances made any reduction of the salt tax improbable.

School Pressure.

Mr. Mundella informed Mr. T. Leighton that Dr. Borham's letter as to cases of alleged death from school pressure had been referred to the London School Board, who were investigating the cases.

The River Lea.

Sir W. Harcourt stated to Mr. Picton that he had communicated with the Lea Conservancy as to the sewage pollution of the river, and had formally certified that it was polluted, but he had no power to do more.

The Case of Mr. French.

Mr. Trevelyan, replying to Mr. Healy, said it was true that Mr. French was recently reported by three doctors to be suffering from mental disease, but that was with reference to his employment in the police. Insanity was no bar to arrest.

The Medical Act Amendment Bill.

On Tuesday, Mr. Gray asked the First Lord of the Treasury whether, considering that notice had been given of a large number of amendments to the Medical Act Amendment Bill, upon which there was likely to be prolonged discussion, it was intended to proceed with the measure this session; and if so, whether he could state upon what day it would be taken so as to avoid the inconvenience occasioned to opponents of the Bill by its

Digitized by Google

being placed upon the notice paper day after day. Mr. Gladstone said that it would be the second order on Monday.—Meanwhile many petitions, mostly in favour of the measure, with amendments, continue to be presented.

Notices.

Mr. Hopwood would on Monday question the Secretary to the Admiralty about an alleged error in the statistics relative to the Contagious Diseases Acts. Sir Trevor Lawrence would ask the Secretary for War whether the regulations for the embodiment of a volunteer hospital corps would be promulgated.

Obituary.

GEORGE ALFRED WALKER, M.R.C.S., L.S.A.

THE death of this gentleman, which, as previously announced, occurred on the 6th inst., at his residence, Ynysfaig House, near Barmouth, serves to sever another link of the chain which binds the medical profession of to-day to that of the early part of this century. Mr. Walker was in his seventy-eighth year, and formerly practised with success in London; he was a staunch supporter of the warm vapour cure, upon which subject he wrote a pamphlet. He, however, was a firm believer that prevention is better than cure, and distinguished himself greatly by the energetic way in which he exposed the sanitary dangers arising from intramural interments in churches and chapels in the metropolis and throughout the country. He was popularly called "Graveyard Walker." In 1840 Mr. Walker was one of the principal witnesses before the Select Committee of the House of Commons on the Health of Towns. He was the author of several works upon this important question, and just before he died was writing another book, a summary of his previous works. He wrote several treatises upon surgical subjects, and for these works he was offered the Fellowship of the College of Surgeons, which he did not accept, as he had retired from practice for many years. He was also a geologist, and was instrumental in opening two quarries, Henddol and Golenwern, which are well known in the district.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 10th, 11th, and 14th inst.:—

Edward L. C. Smith, William H. Duce, William E. Redman, John P. Millington, Richard W. Young, R. H. F. Routh, N. A. Butterfield, T. J. Hall, and P. J. Clark, University College; Henry S. Smith, and Joe Iredale, St. Bartholomew's Hospital; Alexander J. Adie, Thomas Austen, John G. D. Cort, Warburton V. Carden, John Dallewy, and G. P. Barton, Charing-cross Hospital; Brown Clark, Evan J. Williams, and Reginald J. Braye, London Hospital; Edward H. C. Sullivan, Alfred E. Cox, Richard E. E. South, and W. J. Harris, St. Thomas's Hospital; Henry A. Haviland, Cambridge and St. Bartholomew's Hospital; Henry Craig and G. S. Shute, Guy's Hospital; R. W. Cameron, Manchester; E. C. Anderson, St. Mary's Hospital; F. R. Mallard and T. A. Mast, St. George's Hospital.

Of the 234 candidates examined during the past fortnight, 100 failed to satisfy the Board, and were referred for three, and 21 candidates for six months' further anatatomical and physiological study.

COLLEGE OF PHYSICIANS IN IRELAND.—At the July examinations the following candidates obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—George Stamer Browning, Alexander Edward Carte, James Vance Collins, George Patrick Cope, William Henry Clarke, Thomas Joseph Daly, Vernon Kitchen Dearden, Thomas Francis Griffin, Hudson Hairsine, Richard A. Hayes, Thomas Francis Higgins, John Colclough Hoey, Denis Kennedy, Frederick Duncan Lawson, Patrick W. Maxwell, William Cox Neville, Michael Alcock Ottley, Robert Chambers Owen, James Robinson Phillips, William Henry Banner Robinson, Agnes Russell, John Richard Rygate, Francis William Sullivan, John Williams.

MIDWIFERY.—George Stamer Browning, Alexander Edward Carte, William Henry Clarke, James Vance Collins, Thomas Joseph Daly, Vernon Kitchen Dearden, Thomas Francis Griffin, Thomas F. Higgins, Denis Kennedy, Frederick Duncan Lawson, John Joseph Lyons, Thomas Joseph McGrath, William Cox Neville, Michael Ottley, Robert Chambers Owen, William Henry Robinson, Agnes Russell, John Richard Rygate, J. Shackleton, Francis William Sullivan, John Williams.

The under-mentioned has been admitted a Member:—
Lambert Hepenstal Ormsby.

The diploma in Sanitary Science has been obtained by
Thomas Robert Judson.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 10th:—
Marriott, Hyde, Dial House, Stockport.
Samut, Carmel, Floriana, Malta.

AT a meeting of the local authority of the parish of Dundonald, held at Troon on the 5th inst., it was resolved to form a special drainage district.

UNIVERSITY COLLEGE.—Former students of University College will be glad to learn that Sir William Jenner has promised to preside at the annual dinner of the old and present students, which is to be given at the Freemasons' Tavern on Saturday, October 4th.

EAST LONDON HOSPITAL FOR CHILDREN.—Mr. Meriscord has received a letter from the secretary of the above-named hospital, acknowledging the receipt of £60 in all as the proceeds of the matinée at the Avenue Theatre on the 26th ult.

ST. JOHN AMBULANCE ASSOCIATION.—On Monday next, Mr. John Furley will read a paper on the "Carriage and Removal of the Sick and Injured" at the International Health Exhibition, the chair to be occupied by Sir James Paget. On the following Friday, a meeting will be held at the United Service Institution for the discussion of matters connected with the instruction of pupils in the work of the Association.

THE HOSPITAL OF ST. CROSS, RUGBY.—This hospital, presented to the town of Rugby by Mr. and Mrs. R. H. Wood, was opened on the 17th inst., and supersedes the cottage hospital founded in 1869 under the medical superintendence of Dr. Clement Dukes. The new building is constructed on the block system, and, together with the nucleus of an endowment fund, constitutes a gift by the munificent donors of the value of some £25,000.

SEAMEN'S HOSPITAL, GREENWICH.—At the quarterly general Court of Governors, held on the 16th inst., it was reported that 396 seamen had been admitted as in-patients during the past quarter from British and foreign ships. The drainage of the hospital having been condemned by the engineer consulted, a sum of £7370 is required to put it in an efficient state. In addition, it is proposed to erect an entirely new chapel at an estimated cost of £1281.

PRIZE ESSAY OF THE BRITON LIFE ASSOCIATION.—At the general meeting of the members of the Briton Life Association, held on Thursday, July 17th, the award of the adjudicators of the fifty guinea prize offered by the directors for the best essay on "Life Assurance" was declared to have fallen on P. J. Thomson, Esq., M.R.C.S. and L.R.C.P., 14, Rue d'Egmont, Brussels. We congratulate the successful competitor. The adjudicators were Dr. Richardson, F.R.S., Mr. Savory, F.R.S., and Mr. Messent, F.I.A. Thirty-four essays were sent in for the prize.

THE PARKES MUSEUM.—At the annual meeting held on July 9th, a report was read showing the work that had been carried out during the past year, from which it appears that twenty-one lectures have been delivered. The Museum has been largely used by lecturers on Public Health, and by other skilled teachers for practical demonstrations to various classes of students, &c., who for this purpose have been admitted without entrance fee. The members, who numbered 99 on June 30th, 1883, just after the opening of the Museum, now number 260. During the year there have been 6870 visitors.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The second annual dinner of this Society was held on Tuesday, July 15th, at the Star and Garter Hotel, Richmond, under the chairmanship of Dr. J. L. Thudichum, President of the Society. Much amusement was afforded by the *menu*, which had been rendered into classical Latin by Dr. E. Hart Vinen, a feat of no ordinary difficulty. The after-dinner proceedings were enlivened by an excellent programme of vocal and instrumental music, given with much ability by the Misses Thudichum, Mr. Bere, and others. Thirty-five members and visitors sat down to dinner.

Digitized by Google

PROPOSED CONVALESCENT HOSPITAL.—At a meeting held on the 14th inst. at the Mansion House in support of a proposal for the establishment of a convalescent hospital and home of rest for the poor and wage-earning classes of London, it was suggested that 500 beds should be provided in three homes. The estimated cost of maintenance is about £12,000 per annum. The institution is intended for those who, having been under treatment in hospitals or elsewhere, need change of air with a continuance of medical or surgical aid, and for those who, suffering from illness or overwork, require change, good food, and rest; it will be partially self-supporting. A council was appointed to carry out the scheme.

SANITARY INSTITUTE OF GREAT BRITAIN.—At the anniversary meeting held at the Royal Institution, Albemarle-street, on July 10th, Earl Fortescue, Vice-President of the Institute, in the chair, an address was delivered by Dr. H. C. Bartlett, F.C.S., entitled "Some of the Present Aspects of Practical Sanitation"; and the medals and certificates were presented to the successful exhibitors at the Exhibition held at Glasgow in September, 1883. At the close of the address the chairman proposed a vote of thanks to Dr. Bartlett, which was seconded by R. B. Grantham, M.Inst.C.E.; and a vote of thanks to Earl Fortescue for presiding was moved by Dr. A Carpenter, and seconded by Prof. F. de Chaumont, M.D., F.R.S.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly Court of Directors of the Society was held on July 9th, Sir Henry Pitman, Vice-President, in the chair. It was resolved that a sum of £1257 be distributed among the fifty-nine widows, the five orphans, and the three recipients of grants from the Copeland Fund. The expenses of the quarter were £39 17*s*. The Treasurer announced the following donations: Sir Erasmus Wilson, Vice-President, 100 guineas; Cæsar H. Hawkins, Esq, Vice-President, £5 5*s*.; Dr. Bisset Hawkins, Vice-President, £10; and J. Gregory Forbes, Esq., Vice-President, £2 2*s*. Six new members were elected; the secretary reported the deaths of two. Applications were read for the first time from two widows, and grants were made to each. A discussion having occurred at the annual general meeting on the meaning of Law 66, and a wish expressed to have the law defined, the secretary read a letter from the honorary solicitor, Mr Upton, from which it appeared "that eligibility depends on the applicant being the widow or orphan of a person actually a member for three years immediately preceding his decease, and not on the payment of three subscriptions."

Medical Appointments.

Instructions for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ATKINS, GEORGE PURCELL, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Government Medical Officer at Port Lincoln, South Australia.

BAKER, A. DE WINTER, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Dawlish District, Newton Abbot Union, vice A. W. Parsons, deceased.

BASS, FREDERICK, L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Aural Surgeon to the Newcastle-on-Tyne Dispensary, vice Chalmers, resigned.

BEATLEY, WILLIAM CRUMP, M.D.Durh, M.R.C.S., has been appointed Senior Assistant Medical Officer to the Somerset and Bath Lunatic Asylum, Wells.

BOULTER, WALTER ERNEST, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Superintendent to the Woolwich Union Infirmary, vice Rice.

CARROLL, E. R. W., M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Royal Westminster Ophthalmic Hospital.

CHAMP, J. H., M.B.Lond., has been appointed House-Physician to Guy's Hospital.

CLARKSON, CHARLES HOWARD, L.R.C.P.Ed, L.R.C.S.Ed., has been appointed Resident Surgeon of the Hospital for Pacific Islanders in the Mackay District, Queensland.

CLEGG, W. T., M.R.C.S., L.R.C.P.Lond., has been appointed Registrar to the St. Paul's Eye and Ear Infirmary, Liverpool.

CUFF, R., M.B.Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Scarborough District, Scarborough Union.

DAVIES, W. T. F., M.B.Lond., has been appointed House-Surgeon to Guy's Hospital.

DONOVAN, DENIS DEMPSEY, L.R.C.P.Ed., L.R.C.S.Ed., L.A.H.Dub., has been appointed Medical Officer of Health for Cork, vice Cremen, resigned.

FORT, J. WILSON, L.D.S.R.C.S.Eng, has been appointed Honorary Dental Surgeon to the Lancaster Infirmary.

GRAY, C. EDWARD, M.D., Ch.M., has been appointed Government Medical Officer and Vaccinator for the District of Inverell, New South Wales.

HARDY, H. NELSON, F.R.C.S.Ed., M.R.C.S., has been appointed a Divisional Surgeon to the P Division of the Metropolitan Police for North Dulwich and East Dulwich Stations.

HEATON, C. W., F.C.S., has been reappointed Public Analyst for the Parish of St. Martin-in-the-Fields.

JOHNSON, SAMUEL E., L.R.C.S.Ed., L.S.A.Lond., has been appointed Medical Officer for the Moseley District of the King's Norton Union, vice Richard Farncombe, M.R.C.S., L.S.A.Lond., resigned

JONES, M. PARRY, M.B.Lond., has been appointed Resident Obstetric Physician to Guy's Hospital.

KNIGHTS, Mr. J. WEST, has been reappointed Public Analyst for the County of Huntingdon.

MANLEY, J. H. H., M.B., B.C.Cantab, has been appointed Resident Obstetric Physician to Guy's Hospital.

MEYER, C. H. L., M.B., B.S.Lond., has been appointed House-Surgeon to Guy's Hospital.

PHILLIPS, F. B. W., M.R.C.S., has been appointed Resident Obstetric Physician to Guy's Hospital.

POLLARD, W. R., M.R.C.P.E., L.R.C.S.I., has been reappointed Medical Officer of Health for the Rural Sanitary District, Blackburn, and the Urban Sanitary District, Church.

RYLE, R. J., M.B.Oxon., has been appointed House-Surgeon to Guy's Hospital.

SCOTT, T. HARRISON, M.B., B.S.Univ.Dub., has been appointed Assistant-Surgeon to the Adelaide Hospital, Dublin.

TARGETT, J. H., M.B.Lond., has been appointed House-Physician to Guy's Hospital.

WHITTON, JAMES, M.D., L.R.C.S.Ed., has been appointed Surgeon to Mount Ida Hospital, Nasaby, New Zealand.

WORTHINGTON, S., M.B.Lond., has been appointed House-Physician to Guy's Hospital.

WRIGHT, HOLLAND H., L.R.C.P.Lond., M.R.C.S., has been appointed Registrar and Chloroformist to the Evelina Hospital for Sick Children, Southwark, vice R. A. Milligan, L.R.C.P., M.R.C.S., resigned.

Births, Marriages, and Deaths.

BIRTHS.

ADAM.—On the 5th inst., at Fernhead-road, St. Peter's-park, W., the wife of C. Denovan Adam, L.R.C.P.Lond., of a son.

BISDEE.—On the 12th April, at Trincomalie, Ceylon, the wife of Surgeon-Major N. Bisdee, Major Army Medical Department, of a daughter.

BROWN.—On the 8th inst., at Charterhouse, Godalming, the wife of Clarence Haig Brown, M.B., of a daughter.

DEANE-BUTCHER.—On the 16th inst., at Clydesdale Villa, Windsor, the wife of W. Deane-Butcher, M.R.C.S., of a son.

OWEN.—On the 8th inst., at Highfield House, Rushden, Northamptonshire, the wife of Charles R. Owen, L.R.C.P.E., M.R.C.S., &c., of a son.

WHITHAM.—On the 2nd inst., at Adlington, Lancashire, the wife of Alfred Whitham, L.R.C.P., L.R.C.S.E., of a daughter.

MARRIAGES.

CUMMINS—HALL.—On the 9th inst., at St. Michael's Church, Blackrock, Cork, William Edward Ashley Cummins, M.D., eldest son of William Jackson Cummins, M.D., to Jane Constable, second daughter of Robert C. Hall, J.P.

ELLIOTT—HAYWARD.—On the 16th inst., at Sanssalter Church, Whitstable, by the Rev. Wm. Blizard, M.A., Edgar Elliott, M.R.C.S., of Bromsgrove, to Annie, eldest daughter of J. W. Hayward, M.R.C.S., of Whitstable.

HARLAND—BAKER.—On the 3rd inst., at St. Pancras, London, by the Rev. Canon Spence, Henry Harland, M.D., of Calverley-place, Tunbridge Wells, to Emmeline, second daughter of the late Henry Baker, Esq., F.R.I.B.A., and granddaughter of the late Sir Robert Baker, of Montague-place, London.

JOHNSON—SCHREIBER.—On the 9th inst., at the Congregational Church, Stamford-hill, Geo. Lindsay Johnson, M.B., C.B.Cantab., of Upper Norwood, to Emily Maria Schreiber, adopted daughter of the late Rev. M. and Mrs. Symes, of Salisbury.

LUCAS—SMITH.—On the 8th inst., at St. Mark's Church, Hamilton-terrace, N.W., Robert Harry Lucas, M.R.C.S., of Bury St. Edmunds, to Helen Maude, youngest daughter of the late Ambrose Smith, of Blackheath.

DEATHS.

BALFOUR.—On the 15th ult., at Bombay, suddenly, of apoplexy, William Green Balfour, M.R.C.S., L.R.C.P., late of Alton, Hants.

KEELAN.—On the 17th ult., at Roseau, Dominica, West Indies, Nicholas Walter Keelan, L.R.C.P.E., L.R.C.S.I., Government Medical Officer of Roseau, aged 42.

MOORE MILLER.—On the 9th inst., at Southsea, after a short illness, John William Moore-Miller, M.D., M.R.C.P., M.R.C.S., J.P., only son of the late Captain Miller, 40th and 24th Regiments, aged 64.

PARKER.—On the 13th inst., at Pulteney-street, Bath, William Parker, M.D., for many years Medical Officer of Health for Bermondsey, and only surviving son of the late William John Brown Parker, Surgeon, of H.M. 14th Regiment, in his 72nd year.

STAUNTON.—On the 12th inst., at his residence, Waterloo-road, Dublin, Charles Frederick Staunton, M.D., R.A., one of the last surviving officers of the Euphrates Expedition, aged 83.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or notes paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

PROVIDENT DISPENSARIES.

IT is gratifying to know that the Coventry Provident Dispensary continues to prosper. The report of medical work is too general to enable us to say how adequately the medical men were paid, but we learn that they received the following sums respectively: Mr. McVeagh, £334 10*s* 2*d*.; Dr. Fenton, £331 8*s*. 11*d*.; Dr. Davidson, £326 18*s*. 9*d*.; Mr. Pickup, M.B., £518 9*s*. 9*d*.—The report of the Victoria Dock District Provident Dispensary is well drawn up. The impression conveyed is that a good deal of work is obtained from the medical officer and his assistant, and that they get too little for it. They attend the *employés* of many and wealthy firms. They have a total admission of 7455 persons, they pay 5640 visits, and receive respectively £258 1*s*. 6*d*. and £137 10*s*. Such remuneration is not worthy either of the firms or their *employés*. Of the £1980 received for medical purposes only £375 reach the medical men.

A.M.D.—Lyon Médical, vol. 1, 1884.

A TEST FOR ABNORMAL TEMPERATURE OF THE BODY.

To the Editor of THE LANCET.

SIR,—I have recently observed that the organic base triethylamine varies as remarkably according to temperature as to its solubility in water. I must refer those of your readers who are interested in the purely physical aspect of the matter to the July number of the *Philosophical Magazine*. As, however, the property referred to may be of use in the diagnosis of fever, I am bound to make it as widely known as possible. Solutions of triethylamine in water are made of various strengths of from 5 to 12 per cent. of the alkali by weight. These are enclosed in glass bulbs hermetically sealed. All of these bulbs become turbid on being heated, but those containing most alkali require heating least. The turbidity consists in the separation of two liquids—one a solution of water in triethylamine, and the other a solution of triethylamine in water. The 10 per cent. solution becomes turbid at 72° F., the 8 per cent. at 76°; the 4 per cent. requires a temperature of about 107 6°. This range of temperature includes the limits of the possible range of temperature of the human body. In a series of bulbs so constructed, I find, for instance, that No. 6 becomes turbid at 91·4°, while No. 7 requires 98·6°, No. 8 requires 105·2°, and so on. Hence we have a form of heat or fever indicator which may be of use. The remarkable circumstance is that mixture is here undone by accession of heat, and that the minutest change of temperature gives a large separation.

I am, Sir, your obedient servant,

FRED. GUTHRIE.

Science Schools, South Kensington, July 9th, 1884.

SUCCESSFUL VACCINATION WITH FOURTEEN-YEAR-OLD LYMPH.

DR. GOSSET-BROWN sends us the following particulars:—In the year 1870 Mr. Harvey Gosset-Brown, then a student of the London Hospital, vaccinated E. S——. When taking lymph on the eighth day he presented the mother with a well-charged tube, which she carefully preserved. Anxious about her family during the present outbreak of small-pox, Mrs. S—— asked Dr. Newbury Gosset-Brown to revaccinate her husband and three sons. With a view to test the efficacy of the lymph taken in 1870 Dr. N. Gosset-Brown vaccinated the youngest boy, aged nine years, with it. The father and two other sons were vaccinated with calf lymph. In all the effect was satisfactory, and certainly not less so in the youngest boy, upon whom, as before stated, lymph taken fourteen years ago was used.

Incognito.—The questions are very vague; but so far as we understand them, we should be inclined to reply in the negative to both.

THE THAMES AS AN OPEN SEWER.

To the Editor of THE LANCET.

SIR,—The state of the Thames at present is very unsatisfactory; and with the prospect of a considerable period of warm weather presenting itself as not unlikely, it is quite time that some remedy should be attempted. I have been informed that benefit resulted formerly by emptying barge-loads of chloride of lime into the stream; and with some such immediate remedy should be combined the addition to the sewage poured in daily of some chemicals to arrest decomposition. For some weeks past the sewage smell has been steadily increasing, apparently from the hot weather promoting decomposition of the organic matter deposited in the river bed from the sewage as it is carried up and down the river by the tide. For a distance of some miles above East Greenwich and below Crossness sewage outfall, the part with which I am personally acquainted, the water is of a dark opaque grey, and when stirred up by the river steamers gives out a well-marked sewage smell, strong enough to nauseate some persons.

It is not clear that such a state of affairs has any injurious effect on those spending much time on the river, by producing severe diarrhœa or any other form of illness; but it is the duty of every believer in the importance of sanitary reform to try to get rid of "matter in the wrong place," and certainly we have it in the present case. It is to be hoped that the greatest and wealthiest city in the world will not long permit a vast open sewer to run through it, polluting the air and exciting disgust both to sight and smell.

I am, Sir, your obedient servant,

Rotherhithe, S.E. J. A. PHILIP, M.D.

A Young Practitioner.—Excluding grounds of humanity, a medical man is not bound to attend every case to which he is summoned, even where a fee is tendered. To the case described in our correspondent's third question our answer will equally apply; though it might be a serious matter to assume neglect, and refuse on that ground to see a case of advanced disease.

Mr. Laxton.—We know nothing of the work.

"SHOULD ENTERIC FEVER CASES BE ISOLATED?"

To the Editor of THE LANCET.

SIR,—To the above question I answer, Yes. Following the Egyptian campaign (and, indeed, continuing to a less extent up to date) a very large number of cases of this disease occurred among the troops who formed part of the expedition. Many such cases were admitted to the Citadel Hospital at Cairo, and experience soon proved that there was risk to nurses and attendants employed in the hospital, as well as to patients under treatment for other diseases. It then became the rule to treat all cases of enteric fever in separate wards, and this facilitated nursing and enabled the hospital authorities to allot old and seasoned attendants for the management of those cases. We can, I think, easily understand the cause of the danger. We know that patients ill from enteric fever frequently soil their beds and clothing with dejecta from the bowels; and certainly the attendants who have to remove these articles, and even patients in neighbouring beds, must incur some risk from the exhalations from them. I think it is now generally conceded that the poison of enteric fever, or whatever it may be called, can reach the system through the air as well as through fluids &c. swallowed.

I am, Sir, yours truly,

T. F. O'DWYER, M.D.,

Surgeon-Major, Army Medical Department.

Junior United Service Club, July, 1884.

W. A. McNaughten, M.D.—We think our correspondent could have no claim after the lapse of so long a time.

"BOILED LETTUCES."

To the Editor of THE LANCET.

SIR,—It is not plain to many of your readers why spinach should be excluded from the diet of oxaluric patients. I have even ordered sorrel with advantage. Nor is it obvious to me why stewed rhubarb is wrong. The oxalates in these vegetables are soon either voided or decomposed after being taken, and many of the crystals found in them are too large to be absorbed.

I am, Sir, yours truly,

Orchard-street, W., July 15th, 1884. WILLIAM SQUIRE, M.D.

Digitized by Google

ADVERTISING SHEETS.

OUR attention has been called to an advertising sheet which professes to be sent to every member of the medical profession in the United Kingdom. Our correspondent remarks: "I should like to express in your columns my regret at the issue of such a paper. I regard it as very degrading and mischievous to the profession. It would seem that the tendency is now greatly in the direction of making our calling a 'business,' and, as such, to be promoted by advertisement in every form. This modern and American introduction must be firmly resisted if we are to retain the little respect still left to us as a profession in this country."

Mr. McKoll.—Yes; micro-organisms have been discovered in connexion with syphilis and many other affections of a contagious nature.

Mr. Joseph Balfour—The figures quoted are unintelligible.

Mr. Welsham.—The paper has not been overlooked.

ACTION OF BORACIC ACID ON THE URINE.

To the Editor of THE LANCET.

SIR,—Having seen in a medical journal an extract from a communication of some cases which Professor Rosenthal had made to *Allg. Wien. Med. Wochensch.*, Jan. 15th, and in which he had employed boracic acid internally, with a view of checking the formation of ammoniacal urine, I determined to try it when an opportunity arose. The patient on whom I first tried it was suffering from a bad stricture of the urethra, perineal abscess, &c., and on whom perineal section had been performed two or three years ago. His urine on admission was strongly ammoniacal, with flakes of mucus in it. Boracic acid was administered in ten-grain doses every three hours a few days after admission. In about twenty-four hours the urine changed in reaction, and when passing through the fistula recently formed did not scald him nearly so much. Although the boracic acid was continued for a fortnight, no harm resulted from its continuous administration. The urine passed was kept in a vessel for several days without its undergoing decomposition; it also kept its acid reaction. I may add that previous to the administration of the boracic acid the perineal abscess was opened, and the stricture dilated. The man would not submit to any operation for the permanent cure of the stricture.

The other patient is an old woman, who had suffered from cystitis of doubtful origin (no stone) for seven months previous to her admission in this hospital under the care of DR. VINTRAS. Urine was passed every quarter of an hour day and night when she came in. There was much irritation of the labia and inner aspect of the thighs and much scalding on micturition. After trying several remedies with slight success, and the urine being distinctly alkaline and fetid, the boracic acid in ten-grain doses twice a day was ordered. As in the previous cases, the reaction of the urine changed after the first day of taking the mixture, and has continued acid since. The symptoms, too, have been much relieved. In the night now she passes urine six times instead of thirty or even forty times, which she did before. The inflammation between the labia has disappeared, as well as the itching and scalding.

Through the courtesy of Mr. MacKellar and Dr. Vintras, who kindly allowed me to order boracic acid internally in their respective patients above-mentioned, I am allowed to send you these lines, written in the belief that this property of boracic acid is a remarkable and very important one in practice.—I am, Sir, your obedient servant,

GEORGE VICTOR PEREZ, M.B.Lond.
Res. Med. Officer.

Hôpital et Dispensaire Française, London, July 12th, 1884.

H.—1. In most of the States the holder of a respectable qualification is allowed to practise.—2. In Australia and New Zealand registration is required for the recovery of fees, and may be effected on proof of the possession of a British degree or diploma.—3. For an answer to this question we must refer our correspondent to letters which have appeared now and again in our columns.

NECROSIS OF THE MASTOID PROCESS FROM SUPPURATION OF THE EAR FOLLOWING SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—On July 5th, A. B——, aged four, was brought to me on account of the parents having observed that a very offensive discharge was issuing from behind the ear. The child had had scarlet fever rather severely in January, and early in the following month the discharge from the ear commenced, which had continued ever since, being copious and during the last two months offensive; but she had at no time complained of much pain in the ear, nor seemed to suffer much in any way. On examination I found a small opening behind the left ear, with a point of bone protruding, which, it was easily ascertained with a probe, was part of a considerable portion of the mastoid process, and seemed to be quite loose. I enlarged the wound and removed a piece of bone measuring an inch in length and half an inch at the widest part. The discharge from the wound and from the external meatus was free and offensive, but the hearing was very little impaired, nor did the child appear to have suffered much in health. I saw her again four days afterwards, when the wound had nearly healed, and the discharge, which was no longer offensive, had almost ceased.

I have reported this case, thinking it must be an unusual occurrence for the ear to sustain such serious injury and yet recover with so little impairment of function.—I am, Sir, yours obediently,

Congleton, July, 1884. W. M. DAVIDSON.

SANITATION IN CLERKENWELL.

WITH reference to the strictures recently passed in the House of Commons upon the Clerkenwell Vestry by Sir Charles Dilke, and which we reported in our issue of the 12th inst., we have received a letter from Mr. Robert Paget, vestry clerk, containing an emphatic denial of the charges made by the President of the Local Government Board against the sanitary committee. The committee trust that the imputation that the sanitary condition of Clerkenwell is "not only a disgrace, but a danger to the town, and that the vestry is not fit to be trusted with such a position," may be removed as altogether opposed to facts.

M.R.C.S.E., L.M., & L.S.A.—We cannot undertake to say whom the Association should exclude. But the gentleman who certainly does such things as our correspondent describes is not worthy of medical society.

THE PINK FUND.

To the Editor of THE LANCET.

SIR,—Will you kindly publish the subjoined list of gentlemen who have forwarded moneys to me in aid of this aged ex-Poor-law medical officer; and would you permit me to add that, having learned that his friends have raised a sufficiency to keep him from want, it will not be necessary to try the generosity of the profession for any further assistance.

I am, Sir, yours obediently,

32, Soho-square, July 16th, 1884. JOSEPH ROGERS.

Lennox Browne, Esq., Weymouth-street, W., £1 1s.; Dr. Matthews Duncan, Brook-street, W., £2 2s.; S. H. S., £1 1s.; W. Morrant Baker, Esq., Wimpole-street, £2 2s.; J. Smart, Esq., Stamford-hill, N., £1 1s.; Henry Kennedy, Esq., M.B. (Dublin), 5s.; Arthur Eversfield, Esq., Hampstead, N.W., £1 1s.; Sir Erasmus Wilson, Bt. (Westgate-on-Sea), £5; E. B., £1 1s.; R. B. Ruddock, Esq. (Clifton), £1 1s.; R. Mayman, Esq. (Oxford), £1; James Crocker, Esq. (Bingley), 5s.; W. L. Hunter, Esq. (Pudsey), 10s.; W. W. Morgan, Esq. (Newport), 10s.; W. J. Mackie, Esq. (Bedford), £1 1s.; J. Bridger, Esq. (Cottenham), 5s.; H. de V. Balbirnie, Esq. (Sheffield), £1; J. L. Jardine, Esq. (Dorking), 5s.; R. P. Simpson, Esq. (Weymouth), 10s.

Dr. W. O'Keefe.—The question is a legal one. We suspect the legal view might be adverse to our correspondent, but cannot speak with confidence.

J. D, B. should apply to the sanitary authority of his district.

"MIDWIFERY."

To the Editor of THE LANCET.

SIR,—I find from my midwifery case book that Sunday has not been a favourite day for my patients to bring forth. I have taken four years of a country practice in Cambridgeshire, and I find that from 1879 to 1882 the births have been as follows:—1879: Sunday, 16; Monday, 7; Tuesday, 19; Wednesday, 16; Thursday, 23; Friday, 17; Saturday, 22. 1880: Sunday, 17; Monday, 11; Tuesday, 16; Wednesday, 22; Thursday, 16; Friday, 20; Saturday, 25. 1881: Sunday, 25; Monday, 16; Tuesday, 17; Wednesday, 17; Thursday, 31; Friday, 12; Saturday, 19. 1882: Sunday, 10; Monday, 20; Tuesday, 18; Wednesday, 20; Thursday, 25; Friday, 18; Saturday, 21.

In three out of the four years it will be seen that Thursday was the favourite day. In going over the above figures I have been struck with this fact—that whenever I have had three cases in one day it has been a Sunday.

I am, Sir, yours truly,

Bolingbroke-grove, S.W., July, 1884. W. EASBY, M.D.

House-Surgeon.—In the absence of any agreement or custom to the contrary, we think the proposal is reasonable.

M.R.C.S. should bring the advertisement under the notice of the colleges from which the advertising practitioner derives his diplomas.

A Twenty-five Years' Subscriber may apply to Mr. Nock, Bloomsbury-street.

ERGOT AND QUININE IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—There being a divided opinion as to the value of ergot in midwifery, I would suggest the use of quinine as its substitute. I have always been pleased with its effect. It is not a toxic drug, and it is our best preventive of pelvic septicæmia.—Yours faithfully,

Newhaven, July, 1884. FRED. DALTON, L.R.C.P.Lond., M.R.C.S.

Associate of King's College.—The nurse cannot be punished. Our correspondent can claim his fee from the patient's husband.

Observer's views were set forth in a letter which we published last week.

THE CAMBRIDGE SANITARY CERTIFICATE.

To the Editor of THE LANCET.

SIR,—I should like to suggest to the authorities at Cambridge the issue of a syllabus for the above examination, after the pattern of those published by the Science and Art Department (subject "Hygiene"). The present regulations convey a most indefinite notion of what is wanted.

I am, Sir, yours truly,

July 16th, 1884. CANDIDATE.

ERRATA.—In our Paris letter last week Dr. Rochard is represented as saying that the number of "cases" of cholera had been extraordinarily great. The context will show that the word quoted was a misprint for cases. The name "Lamballe" should have been *Liouville*.

Medical Diary for the ensuing Week.

Monday, July 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

Tuesday, July 22.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, July 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, July 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

Friday, July 25.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

Saturday, July 26.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

Remarks
ON THE
PATHOLOGY OF PNEUMONIA AND PLEURO-PNEUMONIA;
WITH NOTES OF EIGHTY-FIVE CASES.

Read before the Liverpool Medical Institution,

BY RICHARD CATON, M.D., M.R.C.P.,
HONORARY PHYSICIAN TO THE NORTHERN HOSPITAL, LIVERPOOL.

PNEUMONIA is so trite and familiar a subject, and in one form or other has been so often brought before this Society, that I can only excuse myself for introducing it again, partly on the ground of the great interest that has always attached to its treatment, but chiefly on that of the new and interesting questions which at the present time are awaiting solution in reference to its pathology—questions which, if decided in the affirmative, will cause us to class pneumonia among the zymotic diseases. For generations this disease has been the chosen battle-field of therapeutists. The bleeders, the givers of mercury, of tartar emetic, and of alcohol, and the disciples of the expectant method have all appeared in turn, and each has claimed a decisive victory. The wide discrepancy of their results has been explained by the well-known theory of a change of type in disease in general. Whether that be true or not, there can be little doubt that there have been many changes of type in pneumonia; that for long periods the disease has presented a mild sporadic form, which, when uncomplicated, terminated in recovery under almost any form of simple treatment. At other times, again, the disease presented a much severer type, which was believed to demand and to be benefited by bleeding and other heroic measures, and to be very fatal if they were withheld; while in other instances the disease has assumed so malignant a type that treatment of any kind seemed of small value. This remarkable variability of pneumonia, while rendering it unsuitable as a test disease for comparison of the results of different methods of treatment, adds greatly to its pathological interest. The resemblance which, in its sudden onset, initial rigor, and rapid defervescence, it has to the class of fevers is rendered much closer, where we find it varying greatly in severity at different times, and occasionally becoming epidemic, and even infectious.

Probably for nearly a century croupous pneumonia in England has been mainly of a mild and sporadic type. Most of our text-books describe this form of the disease; it is unquestionably the one which we usually meet with. Consequently we are rather apt to forget that other forms of pneumonia exist, and if examples of any other type present themselves perhaps we are rather slow to recognise them. The evidence is nevertheless conclusive, that an epidemic pneumonia does occasionally occur in the human subject, and an epizootic form in the lower animals, and that it is occasionally infectious. Among cattle it is perfectly clear that two forms of pleuro-pneumonia exist, the one sporadic, the other epizootic, symptoms, treatment, and ratio of mortality of which have long been known with considerable accuracy; the latter an epizootic form, highly infectious, having a mortality three or four fold as great as that of the sporadic form. It is a remarkable fact that the infectious epizootic form was unknown to English veterinary surgeons until the year 1839, when it suddenly appeared in England and spread rapidly from county to county.[1]

The evidence of similar epidemic pneumonias and pleuro-pneumonias affecting the human subject is very strong. It would be easy to fill pages with accounts of the various epidemics described by Ozanam and other writers, beginning even as early as 430 B.C. with the fatal outbreak of gangrenous pneumonia at Athens described by Thucydides. But I will merely mention with great brevity two, which are quoted from older authors in *Dr.* Sturge's work on Pneumonia, and then pass on to speak of recent epidemics which have been observed by men who studied and described them in the light of modern pathological knowledge. The Belgian epidemic in 1557 was characterised by "vehement cough and fever, pain in the side, and difficult respiration; bloody expectoration occurred on the third day, and death on the fifth to the eighth, unless bleeding was performed on the first or second day," bleeding at a later stage was held to be useless. The Philisbourg epidemic of 1688 was characterised by "stitch" in the side and chest oppression; the disease terminated, in fatal cases, about the eighth day, in delirium, convulsions, or diarrhœa. The lungs were found "actively inflamed and hepatised, in many parts purulent, the chest and pericardium filled with bloody serum." In most of these reports of ancient epidemics of pneumonia it is to be noted that when post-mortem appearances are described, there was fluid in the pleuræ and pericardium.

Among the modern epidemics is that which occurred in the Mediterranean Fleet in 1860, and which Dr. Bryson describes in THE LANCET for Jan. 9th, 1864. It was a fatal form of typhoid pneumonia, often accompanied by effusion into the pleuræ and by diarrhœa and dysentery. Its resemblance to the pleuro-pneumonia of cattle was specially remarked. It was believed that the sick landed at Malta gave the disease to other inmates of the hospitals.

The Iceland epidemic of 1863 is interesting. My old friend Dr. Hjaltelin has often mentioned it to me. He describes it fully in the *Edinburgh Medical Journal* for April, 1864. Pneumonia, like all chest diseases, except hydatids of the lung, is rare in Iceland; but when it does occur it is in a most fatal epidemic from. In 1863 the disease prevailed to a frightful extent among the Icelanders. The main lesions found after death were extensive hepatisation and quantities of lymph and serum in the pleural cavities. Dr. Hjaltelin was in the main an opponent of bloodletting, but in this epidemic he came to the conclusion that it was necessary; he found that if it were omitted the patient generally died on the second or third day. There were at that time only eight medical practitioners in the whole of the island, consequently numbers of the sick had no professional attendance; and amongst them Dr. Hjaltelin describes the mortality as being very high; for example, in one parish out of twenty-four cases seventeen deaths occurred. Knowing from experience the extreme severity of the climate and the miserable huts in which the Icelanders live during their nine-months' winter, it is a matter of much surprise to me that sporadic pneumonia is so rare.

Dr. Kühn of Moringen, in Hanover, reports an outbreak which occurred in that town in 1878. Forty-five cases occurred. The disease was marked by great prostration, enlargement of spleen, and albuminuria; there was almost always pleuritic effusion. Pericarditis occurred in one-fourth of the cases, meningitis in one-ninth, and diarrhœa in two-thirds. It was distinctly infectious. In addition to the lesions named above, parenchymatous nephritis and fatty degeneration of the heart were frequently found at the autopsies.[2]

In the year 1881 an outbreak occurred at Lustnau, near Tübingen. Among a population of only 1600 forty-four cases occurred, and of these ten were fatal. If time and space permitted many other instances might be quoted, as for instance, the Christiania epidemics of 1847 and 1866, also that recorded by Dr. F. H. Daly in THE LANCET for Nov. 12th and Dec. 24th, 1881, where six persons in one house to all appearance contracted pneumonia from one another, just as they might scarlatina or typhus. In many of these epidemic outbreaks there is evidence of the prevalence of cold winds and severe weather at the time, in other cases no such exciting cause appears to have existed.

Passing from the subject of the epidemic and infectious forms of pneumonia, I wish next to speak of the pathological problem referred to in the opening paragraph—viz., the supposed origin of pneumonia from a specific micro-organism.

In the year 1875 Professor Klebs of Zurich described in the fourth volume of the Archives of Experimental Pathology certain micro-organisms which he had observed in inflamed lung, and which he named "monas pneumoniæ." A little later Eberth saw the organisms in the lung and in the pleural effusions of a case of pneumonia, and described them in the twenty-eighth volume of the Archives of Clinical Medicine. Koch also gives an account of them in the Reports of the Imperial Health Department for 1881. Dr.

1 Sturge's Lecture on Cattle Diseases.

2 THE LANCET, August 24th, 1878.

Friedlander, Privat Docent in Pathological Anatomy in Berlin, and Dr. Frobenius likewise publish detailed accounts of cases of a severe form of pleuro-pneumonia in which in the lungs pleural effusion and lymphatics were found quantities of an elongated micrococcus, the organism being often seen in pairs or chains, and enclosed in a mucigenous envelope. Friedlander and Frobenius succeeded in cultivating these organisms in blood, serum, and in other fluids, and they then proceeded to inject the micrococcus into the lungs of various animals. Five dogs were experimented upon; one of them died of pleuro-pneumonia. Several rabbits had the injection made into the lung, but without result. Guinea-pigs were tried, and about half the number were seized with pneumonia. A large number of mice were inoculated, and in every instance fatal pleuro-pneumonia followed; the consolidated lungs and the pleural effusion were found full of the micrococci. Mice were placed in an atmosphere into which the micrococci were thrown by a spray producer, half of those inhaling this atmosphere contracted pleuro-pneumonia.

There thus exists a certain amount of evidence that some or all cases of pneumonia depend upon the presence of a micrococcus, but the evidence cannot as yet be regarded as conclusive. The problem is a very important one, and one which it may be hoped physicians and pathologists will speedily solve. Many of the cases in the annexed table would have afforded an excellent opportunity for investigation, but most of them occurred at a time when little or nothing was known of a pneumonia micrococcus. The sputum of Cases 84 and 85 was found, when treated with gentian violet and iodine, to contain multitudes of micrococci, but whether or not they were the true specific organisms of pneumonia it is not possible to say. The series of cases given includes every case, complicated or uncomplicated, which I have had during the past seven years, with one exception. Owing to imperfection of records, the details are not quite complete. In some of the fatal cases either an autopsy was refused or no notes of it were preserved. It need hardly be remarked that I do not bring these cases forward as an example of a low mortality and successful treatment, though I believe the treatment was as successful as we could anticipate in the class of cases treated. The chief interest of the table consists in the extremely high mortality which prevailed at certain times, and in the remarkable variation in type which the disease presented in different years.

Before passing on to the principal deduction which I propose to draw from these cases, there are one or two minor points to be mentioned, and the first is this. Most of our pneumonia cases at the Northern Hospital are sailors or dock labourers. Many of them are habitually intemperate; where the patient confesses intemperance his testimony may generally be accepted; when he denies it his evidence cannot, perhaps, be always taken so unreservedly, as was made manifest by a patient of mine who did not regard himself as by any means a drunkard, but who was found, on careful cross-examination, to have habitually taken three quarts of rum or whisky daily. It will be seen, on referring to the table, that almost every confessedly intemperate man either died or suffered some complication. The second point is this. At the Northern Hospital we receive a great many drowning cases, and many of them take pneumonia. In fact, it is a routine practice with us to keep these people in bed for at least four days. It will be seen that my list includes twelve of these cases. They are nearly always intoxicated at the time of the accident, and in many the immersion was a prolonged one. The chief point of interest in these cases is that we are able to watch the physical signs from the beginning of the disease, and the first indication is diminished respiratory murmur on the side which is about to be attacked, this is followed by slight harshness, and then later come the crepitation and dulness. Thirdly, many of the deaths—as, for example, Nos. 15, 21, 52, 53, and 79—may be put down quite as much to antecedent disease of other kinds as to pneumonia; also many of the cases came in late in the course of the disease, and had been under very unfavourable conditions prior to admission. Still, making allowance for all these special causes of mortality, the death-rate remains very high.

Now, I come to the chief point to which I desire to direct your attention. During certain periods of the seven years over which the table extends I was much struck with the malignant form which the disease presented: Case 8 was the first of the kind. Both lung and pleura were involved. There were diarrhœa and extreme prostration, and after death we found the lung in a softened and almost rotten condition, and the serum in the pleural cavity putrid and offensive. After this no specially malignant case occurred until 1879, when seven cases of pleuro-pneumonia were admitted among a total of thirteen cases, and of these seven died. During the succeeding twelve months the cases were of a milder kind and only two deaths occurred, but from the end of December, 1880, throughout 1881, and up to January, 1882, nearly every case admitted was of a most severe type. Out of a total of seventeen cases ten were pleuro-pneumonia, and out of the whole number of seventeen only four recovered, notwithstanding our utmost care. I need scarcely say that so frightful a mortality occasioned great concern in the minds of all who had to do with these cases, and that we used every endeavour to save them. Subsequently to January, 1882, the disease became much milder in type, the pleura being rarely involved, and during the two years and a quarter that have succeeded I have had only two deaths—viz., Case 69, a poor girl who died after a premature confinement; and Case 79, a drunken publican who was brought in almost dead after long immersion, and, in addition, comatose from a head injury. These, strictly speaking, are not pneumonia deaths at all. During 1879 and 1881 I was fully convinced that we had to do with a malignant and septic form of pneumonia, for the following reasons—(1) the extreme prostration of the patients, (2) the frequency of pleurisy—out of twenty-nine cases the pleura was involved in sixteen; (3) in three cases meningitis occurred, and in two pericarditis. Albuminuria, delirium, and diarrhœa were also common. How abnormally frequent these complications were may be seen if we take as a basis of comparison 8000 consecutive cases of pneumonia tabulated from the Reports of the *Allgemeine Krankenhaus* in Vienna. Among these pleurisy occurred in 5 per cent., meningitis in 1 per cent., and pericarditis in 1 per cent. In many respects the severe cases occurring in the years 1879 and 1881 resemble those described during epidemics of pneumonia, but I saw no clear evidence of infection. Selecting twenty-nine of the severest cases I found that five came direct from ships in the docks; that the residences of eight were widely scattered at long distances from one another, in different parts of the city; that a group of six cases all came from one very limited area within a radius of a hundred yards, that another group of five cases came from another still more limited area, while the remainder lived near the two last-named centres. The following table of the pneumonia deaths in the Liverpool Hospitals, taken from the return of the medical officer of health, shows that the years 1879 and 1881 were years of great mortality:—

Year.	Workhouse.	Infirm.	Northern.	Stanley.	W. Derby	Southn.	Total.
1876	38	7	3	...	5	10	63
1877	54	9	4	...	4	8	79
1878	85	12	7	3	4	7	118
1879	86	9	11	...	16	12	134
1880	...	...	No return		...	...	...
1881	114	8	9	2	22	17	172
1882	94	9	9	2	17	4	135

The pneumonia deaths rose from 63 in 1876 and 79 in 1877 to 134 in 1879 and 172 in 1881, and after that diminished. Dr. Robertson, physician to the workhouse, tells me the returns from that institution are not to be entirely depended upon; but even if we omit them altogether, the death-rate of the other hospitals is still found very high in 1879 and 1881. I do not know how to account for the great fatality of pneumonia during these years. It is true that Niemeyer has remarked that the disease is always more severe during the existence of an epidemic of typhus, and typhus was prevalent in Liverpool at this time. Whether we are entitled to say that pneumonia was epidemic during those two years may be open to question—personally I think it was; but as a matter of fact there is no doubt it was severe in type and very fatal.

In conclusion, I should like to say a word or two as to the treatment of these cases in the hospital. In the first place the patient is put into a comfortable bed in a warm part of the ward; he is carefully nursed by night and by day, visited once daily by the honorary physician and four or more times daily by the house-physician. His temperature, pulse, and respiration are noted twice daily during the acute stage. In

the few instances in which the case is seen at the onset of the disease, mustard poultices and the internal use of aconite and spirit of nitre, or other remedies having a like action, are given with the view of checking if possible the severity of the attack. In general, however, acute fever and consolidation of lung are present when the patient is admitted. Great care is taken to avoid chill during the first and all subsequent examinations of the chest. The state of the lung having been ascertained, a jacket poultice is applied to the side affected, and this is renewed every four hours. A milk diet is given during the acute stage. If the heart's action be feeble, and particularly if the first sound be indistinct, stimulants are given, the amount and frequency being determined by the special needs of the patient. In cases of great feebleness brandy is given every two hours, every hour, or even every half hour. Carbonate of ammonia is given in five-grain doses about every four hours, along with senega, spirits of nitre, or other drug that special symptoms may render suitable. If the cough is very irritating and pain is severe, while there is no evidence of accumulating fluid in the air-passages or of kidney complication, small doses of opium are given. I have rarely employed bleeding. Case 47, however, was an exception. The patient was a robust man, attacked with a double pneumonia, who came in much cyanosed and gasping for breath, with fifty respirations per minute; the veins of the head and neck were much distended, and he was scarcely able to speak. During the next half hour he continued to get worse. Eight ounces of blood were taken from the left median basilic vein. Great relief followed, respiration slowed, and the patient became able to speak easily and comfortably. In a few hours his respirations fell to twenty-eight. In sthenic cases considerable danger may arise from the over-distension of the venous system and of the right heart, due to the great obstruction which the blood meets in its passage through the lungs. Moderate bleeding under these circumstances lowers tension to a slight extent in the venous system, and enables the right heart to overtake its arrears. In some epidemics of pneumonia, notably in the Icelandic outbreak described above, this condition was probably very common, and doubtless Dr. Hjaltelin was perfectly correct in saying that those in whom this venous congestion was relieved by an early bleeding recovered, whereas if it were not relieved the embarrassed condition of the heart added greatly to the peril of the attack.

I am fully convinced that it is a mistake to lay down any one special course of treatment as the right and true one for all cases of pneumonia, or to suppose that such treatment if wisely directed must always succeed. In ordinary uncomplicated cases of sporadic pneumonia the course of treatment described above is most successful, and the death-rate is very low, as shown by the excellent results of Professor Bennett, of Dr. Waters, and of many other physicians; but let pneumonia appear in an acute epidemic form among a full-blooded country population, and be ushered in by such intense venous congestion as we had in Case 47, then doubtless bleeding at the onset is the right treatment, and probably of more avail than anything else we can do. Or again, let a severe form of epidemic pneumonia occur in a town population and be accompanied by effusion into pleura and pericardium and by meningitis and the other complications I have described, then the treatment described may be the right one; at any rate I fear we do not at present know of any that is better, but it will not prevent the death of a large proportion of the sick, however wisely and carefully we conduct it.

METEOROLOGY IN RELATION TO HEALTH.—At a conference on this subject held recently at the International Health Exhibition, Dr. Tripe gave a number of statistics derived from his own observations dating from 1847, showing the relation between changes of temperature and certain specific diseases, such as scarlet fever, which seemed to be checked by a low temperature, while a sudden fall of the thermometer was connected with an increase of deaths from lung diseases. Mr. G. J. Symons read a paper on English Climatological Stations, in which he described the apparatus required for making meteorological observations. At an adjourned meeting of the conference, papers on "Equinoctial Gales—do they occur in the British Isles?" and on "Some Occasional Winds and their Influence on Health," were read by Mr. R. H. Scott and Mr. W. Marriott respectively.

ACUTE TRAUMATIC MALIGNANCY.[1]

BY LAMBERT H. ORMSBY, M.D., F.R.C.S.,
LECTURER ON CLINICAL AND OPERATIVE SURGERY, AND SURGEON TO THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY, AND TO THE CHILDREN'S HOSPITAL, DUBLIN.

THE predisposing and exciting causes of carcinoma, sarcoma, and other species of malignant disease, and the rapidity of their growth, have always been a subject of the deepest interest to the practical surgeon. Theory after theory has been promulgated, cause after cause named as the exciting agent in the production of this diseased condition. However, little has been added to our state of knowledge of recent years, notwithstanding the advances made in pathological research, to account more definitely or more accurately for its production and commencement in the bodies of certain constitutions. The doubt as to whether it is altogether a constitutional malady, or whether it is a disease assisted and encouraged by local effects, having at the same time a hereditary constitutional origin, being a combination of the two factors, seems to me still to exercise the minds of modern surgeons as it did in the past.

Some two years ago I happened to read a paper[2] on this subject from the pen of Mr. Richard Barwell, senior surgeon to Charing-cross Hospital, and since then I have paid particular attention to certain clinical characters and conditions of malignant tumours of the sarcomatous and carcinomatous group which have come under my observation, and in some of these cases I certainly could distinguish a remarkable difference in the extraordinary rapidity of their growth, such development following quickly after the receipt of a blow or other injury to the part affected, so much so that I feel the title of this communication correctly denotes a class of malignant growths clearly distinguishable from the rest of the generic species by the rapidity of its development after local injury.

Mr. Barwell, in his introductory remarks in the paper alluded to, says: "The cases on which the name is founded made a great impression on my mind, leading me to think that occasionally under the stimulus of severe irritation the tissue elements, which under favourable circumstances would assume only the additional activity necessary for repair, may exhibit a more prolific cell germination, culminating in a rapid form of malignant disease in one of those forms, whether named myeloid or round-celled sarcoma or encephaloid cancer, which consists of little else than heaped-up cells and their progeny."

In the following cases it will be found that malignant tendencies rapidly developed after the receipt of local injury. I would, however, be inclined to think that, without some inherent malignant constitutional tendency, a local injury would not be followed by anything more than some slight temporary benign irritation and inflammation necessary for the healthy reparation of the part. For it would appear, according to Billroth, that the development of tumour depends upon two factors: (1) the inherent tumour-forming diathesis; (2) local irritation, which may be either inflicted suddenly or may be of long-continued duration.

As already mentioned, in healthy individuals we find local injuries, such as wounds and blows, merely go through the benign and natural processes sufficient for repair, such as inflammation, ulceration, suppuration, and cicatrisation, and such injuries produce no bad constitutional or local effects whatever. On the other hand, in patients with a constitution having a hereditary tendency to tumour diathesis, small skin wounds and other slight injuries are rapidly followed by a very fast-growing malignant tumour at the original seat of injury. From this, then, it would seem that although the tumour diathesis may be present in the body of a given individual, the condition may be harmless for a certain limited time, or for a very considerable period, as it requires another factor to complete the process of malignant development, and such factor, it would appear, is frequently contributed by a traumatism or other local irritation of one kind or another; and should the latter factor of local irritation be wanting, no malignant development takes place.

Take, for example, the lower lip, a very common situation

[1] A paper read at the Surgical Section of the Irish Academy of Medicine, May 9th, 1884. [2] British Medical Journal, Feb. 11th, 1882.

among certain classes for epithelial cancer to make its appearance. In early stages, and up to a certain point, I would think that only the tumour diathesis was present—in fact, that it was in a pre-malignant condition. To this add the factor of continual local irritation by means of the heated stem of a short clay pipe, and you have epithelial cancer very rapidly developed. Also, in malignant tumours of the breast, the tumour-producing diathesis may be present for a considerable time, and no malignant development take place until a blow or other injury is received at the part, and rapid enlargement and growth follow. The following appear to me to illustrate the subject of my paper.

CASE 1.—B. H——, a young gentleman, aged ten, in the month of June, 1869, fell off some rocks at the sea-shore. In falling he came in contact with a large stone, which struck his right leg about two inches below the tubercle of the tibia. He felt the place rather stiff and painful for two or three days after the injury, which was treated by cold lotions, bandaging, and rest. However, the pain never altogether disappeared, and in about a fortnight the whole circumference of the limb began to swell, and the seat of the injury, on the front of the tibia below the knee, became very painful. He was unable to walk, and began rapidly to lose flesh and appetite. The limb by this time had become considerably enlarged, glazed, and tense, with large blue veins coursing over its surface. About the end of July his father consulted the late Mr. Adams, who recommended that Sir George Porter should also be consulted. At this time the nature of the case was clearly defined, being considered by the surgeons mentioned to be a rapid development of malignant disease of the tibia, at the seat of injury. Amputation at the lower third of the thigh, above the knee-joint, which was already more or less implicated, was suggested as the only means available to save the little patient's life. The father, however, would not consent, but took the child to London, where he consulted Sir James Paget and Mr. Cæsar Hawkins, who also recommended that amputation should be performed. After remaining in London some few days, the father brought the boy back to Dublin, who by this time had become very much weaker and more emaciated, being apparently worn out by the incessant pain and sleepless nights. At the request of the father the limb was amputated at the lower third of the thigh by Sir George Porter, assisted by the late Mr. Adams, Mr. William Stokes, and myself. The boy recovered the shock of the operation, but sank three weeks afterwards from sheer exhaustion. In this case the patient was apparently in the best of health up to the time of the fall, and from that period rapid development of malignant disease (fungus hæmatodes) set in, and he died within three months of the receipt of the local injury.

CASE 2.—Robert F——, aged twenty-five, was admitted to the Meath Hospital from the county Kerry on March 18th, 1884, under my care, suffering from an enormous tumour growing from the left side of the neck. His previous history was as follows:—About ten months before he received a severe blow of the fist on the left side of his neck, and from that time he felt pain and uneasiness in the part. A slight swelling soon appeared and grew rapidly till it reached its present dimensions, as depicted by photograph, which was taken while in hospital. His family history was good; none of his relatives were affected with cancer; he has had to work very hard, subjecting himself to much wet and cold. Latterly, he thought, the tumour had increased more rapidly in size, it had become very painful, and he had lost flesh. He had difficulty in swallowing owing to the encroachment and pressure of the tumour internally on the fauces. Several consultations were held with a view to decide as to the propriety of an attempt being made for its removal. He was exhibited at a meeting of this section, and several members present saw him. However, it was considered advisable not to operate, as the operation would necessitate the removal of the entire lateral aspect of the neck. The patient on hearing the decision regarding his case left the hospital about April 24th, 1884, for the country, without having any operation performed.

CASE 3.—Thomas N——, aged forty-nine, was admitted to the Meath Hospital from Roscrea on Sept. 11th, 1883, under my care, recommended by Dr. Powell of Roscrea, suffering from an obscure, doughy, tense enlargement of the lower inner third of the left thigh. In June of last year he was working as a navvy on a railway, where he received a severe blow on the inside of his left thigh, at the seat of the present swelling. The part was painful for a few days, when the uneasiness passed away. However, the limb always remained swollen at the point of injury, and slightly stiff. He received the blow in June, and about the middle of August he experienced great uneasiness, with sharp darting pains through the part. He then applied to Mr. Powell of Roscrea, who sent him up to the Meath Hospital. On admission, the man was rather debilitated, having lost much flesh lately; his left knee and lower part of the thigh were a good deal swollen, with large blue veins distinctly visible over the surface. As the swelling was rather obscure at first, rest, tonics, and strapping the enlargement with compound mercurial ointment were tried, but with no effect. He complained of the bursting tense pain of the tumour, and thinking there might be some fluid present I accordingly, on Oct. 9th, 1883, made an exploratory puncture with trocar and cannula, and removed a large quantity of dark-coloured bloody fluid, which gave him great relief. But the tumour continued to enlarge rapidly, and the clinical characters of the tumour were becoming manifest, as was verified afterwards by a careful microscopical examination by Mr. Abraham, that it was an ossifying sarcoma. A consultation of my colleagues was held, at which consultation Mr. Wm. Stokes was present, when it was decided to recommend amputation at the upper third of the thigh. The patient on hearing this said he would rather die than allow the limb to be removed. He accordingly left the hospital for the country about Oct. 20th, 1883.

On Jan. 3rd, 1884, the man returned to Dublin, and was admitted again to the Meath Hospital in a very much worse state. He seemed greatly worn out with pain. He said that he was now quite determined to allow the limb to be amputated, as he could no longer endure the pain. The tumour had increased considerably, and its clinical appearances were well-marked. Accordingly, on Jan. 7th, 1884, I amputated the limb by the circular method at the upper third of the thigh, with full antiseptic precautions, and the man made a rapid recovery, and left the hospital at the end of February last. It was remarkable how quickly he recovered health and strength after the limb was amputated, no doubt owing to the removal of the excruciating pain he experienced in the limb before its removal. He had been perfectly healthy up to June, 1883, when he received the local injury, and from that time the malignant character of the tumour was clearly defined in the course of three months.

CASE 4. — Francis J——, aged fifty-eight, a farmer from Kesh, was admitted to the Meath Hospital, under my care, on Sept. 24th, 1883. On Dec. 10th, 1882, during the hard frost, he fell with great force on the point of his left shoulder. It was a little sore at the time, but gave him no trouble till five weeks after the accident, when the shoulder began to swell and grew very painful. He then went to the local practitioner, Dr. Geo. Leeper, who applied anodyne liniments, followed by blistering. This gave him some slight relief, and, acting on his advice, the man went into the County Infirmary at Enniskillen, where he was poulticed and afterwards blistered. He, however, did not improve, and left the infirmary, after remaining there for seven weeks, to return to his home. He then, by the advice of his friends, applied poultices of herbs to his shoulder, which produced suppuration at the part. At this stage Dr. Leeper was sent for, who made an incision in the tumour and gave free exit to a quantity of very offensive pus, after which the swelling in the shoulder went down considerably, and he felt better in every way. While under Dr. Leeper's care a piece of diseased bone found its way to the surface. Dr. Bagot of Enniskillen saw the man at this time, and recommended him to seek admission to a Dublin hospital.

On examination, the contour of the shoulder was found very much changed, presenting an immense lobular malignant-looking enlargement (probably sarcoma), with a tense, semi-elastic surface, resembling a boiled leg of mutton, with large veins coursing over it. The glands in the axilla were also implicated, and became merged into the swelling. There was also a constant discharge of thin sanious pus, from two small openings where the piece of bone was removed. The disease and enlargement extended from the insertion of the deltoid along the clavicle and down the great pectoral muscle, across the anterior fold of the axilla, round the arm, to the posterior fold of the axilla and scapula as far as the attachment of the deltoid to the spine of that bone. On September 26th, 1883, two days after admission to the Meath Hospital, a full consultation was held on the man's case. The only operation that could have been performed was amputation at the shoulder-joint,

Digitized by Google

but as the disease had extended to the pectoral muscle on the front of the chest wall, as well as implicating the scapular muscles behind, it was thought such an operation would fall short of removing the entire disease, and further, as the patient was so reduced in strength and emaciated by the constant pain, it was considered that he would not be able to undergo such an operation. Tonics were administered and the shoulder poulticed, and on October 15th, 1883, he returned home to the country, where he died a fortnight afterwards quite suddenly, probably from an embolism. In this case the man was in the best of health up to the time of injury, on December 10th, 1882, and he died a little over ten months after the accident, of undoubted malignant disease.

In the foregoing cases it will be seen that in each instance there must have been the tumour-forming diathesis present when the injury supplying the local irritation was followed almost immediately not merely by a slow chronic growth of tumour, but by a rapid development of local malignancy. And in bringing this subject before the members of the Academy present, I am anxious to elicit their opinion as to what part the factor of social injury or irritation plays in the rapid production of malignant disease.

THE ETIOLOGY OF TETANUS, AND THE OCCASIONAL VALUE OF NEURECTOMY IN ITS TREATMENT.

BY J. A. MACDOUGALL, M.D., F.R.C.S.ED.,
CONSULTING SURGEON TO THE CUMBERLAND INFIRMARY, ETC.

(*Concluded from page 100.*)

THAT many experiments have failed to induce tetanus in animals is deservedly regarded in the light of a result markedly antagonistic to the theory of its nervous origin; but still, considering how rare a sequel it is when one contemplates the very large number of traumatisms arising from day to day, and that the animals experimented upon must have been comparatively few in number, and with nerve centres, even spinal, somewhat differently constituted from those of man, the success which Brown-Séquard, Weber, and Heidenhain have obtained by different methods in inducing it serves to demonstrate that certain forms of irritation may undoubtedly give rise to the disease. In connexion with this nervous theory of tetanus there is one matter which to me seems difficult of explanation. No organ is more sensitive, none more rich in nervous supply, than the eye; and in none is lesion, if happening in one particular region, so certain to be followed by nerve harm. The possibility of the occurrence of sympathetic ophthalmia is ever and again a source of anxiety to the ophthalmic surgeon. How comes it, then, that tetanus, either in connexion with injury to or operation on this special organ, is so rare that, after somewhat diligent search, I have quite failed to find any reference to it? There seems nothing in the anatomical constitution or relations of the ciliary nerves rendering them less susceptible of originating such harm than those having their distribution, say, in the mucous lining of the nose. Impossible, then, as it seems to accept any one theory as explaining every case of tetanus, and yet obviously of the highest moment as regards our treatment that the probable source should be carefully sought after, and, if found in peripheral irritation, dealt with, if possible, by surgical procedure, I record as of interest the following cases.

CASE 1.—In the spring of 1878 a patient came to me from the neighbourhood of Keswick complaining of severe pain in the front of the right leg, with a certain numbness and inability to use the limb. Examination revealed, about an inch and a half below the tuberosity of the tibia and to its outer side, a distinct enlargement, firm in consistence, limited in size, and exquisitely painful when pressed upon. The pain thus created was the same, the patient stated, that interfered with her walking. Its situation, the history she gave, and the characters it presented, all led me to believe it was a neuroma, and she was advised to have it removed. This was done on the following day, and a tumour, the size of a small pigeon's egg, was removed along with about half an inch of the anterior tibial nerve, from which it sprang. The artery which lay behind and in very close relation to the tumour was unfortunately wounded, and, as one or two primary attempts to secure it failed (for it lay in the floor of a deep wound), the suspicion rested with me that the extremity of the divided nerve might have been subjected to irritation. The wound was treated antiseptically. For a week she did well; the incision had almost healed, and she was quite free from all suffering. Then came a sense of stiffness in the jaws and neck, epigastric pain, rise in pulse and temperature, rigidity of muscles, and ultimately severe tetanic spasms. She was treated with chloral and bromide of potassium in very full doses, but with little effect; and so rapidly and acutely did the disease develop, that it was evident unless something could be done the end was not far distant. I therefore divided the external popliteal nerve in the ham. For thirty-six hours after she improved; her spasms were less severe and came at longer intervals, and a hope was cherished that she might yet do well. But unhappily, in spite of undoubted amendment, there came one spasm either more severe than those which had preceded it, or affecting more than they had done the especial muscles of respiration; at all events, she died suddenly, apnœa being the immediate cause of death.

CASE 2.—Little more than a year after the death of Case 1 I saw, with another surgeon, a lad who had a few days before my visit received a lacerated wound on the posterior aspect of the radial side of the wrist, in the region of the distribution of the radial nerve. What had struck his medical attendant from the beginning was the pain he suffered each time the wound was dressed. On the morning of our visit he complained of stiffness of his jaws, and he had undoubtedly stiffness of the muscle of his neck. He had also a slight rise in temperature with a little quickening of pulse, and the expression of his face was drawn and rigid. The dressings were undone, and although they were removed with great gentleness, the pain darting up the arm from the injured point made him scream. Examination with a probe detected in the floor of the wound one spot where when pressure was applied the spasm and the pain became intense. Closer inspection revealed a nerve, probably one of those passing to the thumb, lacerated and well-nigh divided. The injured portion was exsected and the dressing reapplied. The sufferings of the boy ceased at once. Within twenty-four hours the stiffness of the neck and the jaws disappeared, and when I saw him again the very brightness of his face told how much suffering and peril had, on the occasion of my former visit, been his. With the exception of an aperient, he had no medicinal treatment.

CASE 3. (This case is related, as will be more fully explained in the context, very reservedly as one of tetanus.) Not many weeks ago a table-maid consulted me in these circumstances. Two days before her visit she had been seized with sudden and painful spasm in the hand, the spasm beginning by extreme flexion of the ring and little fingers. This had extended to the arm; and so severe and uncontrollable had it become, that on the day I saw her she had upon two occasions dropped the tray she was carrying. On questioning her this was her story:—A week or ten days before I was consulted a needle pierced deeply the mass of the muscles forming the hypothenar prominence, and she believed that in the attempt to withdraw it, an attempt so far successful, a part of it broke off. She certainly had in one spot severe pain on pressure, a pain which at once gave rise to more or less spasm. Under chloroform, and guided by this painful spot and by a certain hard feeling in it, I made a search for the needle point, but failed to find it. Confident, however, that by irritation of some nerve filament it was occasioning the spasm she described, and might lead to more serious consequences, I turned the knife transversely in the wound and divided deeply all the textures in its line. From the moment this little operation was performed she was well, and it is only within the last few days that I have been able to assure myself that she never had afterwards, in any way, the smallest discomfort.

The improvement in Case 1 after the operation was notable and decided; and although it terminated fatally, it terminated, as I once heard remarked by a distinguished surgeon with reference to a case of tetanus under his own care, "when it was getting well." And such a result is not difficult to understand, for we know that the ordinary recovery from tetanus is slow and gradual, and that it is marked by the very conditions this patient presented, lengthening intervals between the spasms and less violence in their attack. Nor can we expect the disease, if fully developed,

Digitized by Google

and developed in its highest manifestations, to yield at once in every case even when the source of excentric irritation has been cut off. Impossible as some have found it to verify the observations of Clark and Coats, the accuracy and the skill of these investigators are so well recognised and so indisputable that we cannot but believe that the lesions they have described had the fullest existence. Given, then, such structural changes as the direct result of excessive activity of the spinal nerve-cells, there seems a fair presumption that a reflex excitability once established in so uncontrollable and exaggerated a degree, and possibly perpetuated by the anatomical changes which it has induced, will of necessity take a certain length of time to pass away. During this slowly advancing period of recovery spasms will occur, and so occurring, may unhappily terminate the life of the patient. I am not sure that in some cases of puerperal eclampsia we have not a very similar condition. The nervous system of the pregnant woman is in a high state of reflex excitability, so much so that, after excluding by careful examination all evidence of renal harm, it is difficult in some instances to explain the occurrence of convulsion upon any other supposition than that labour, acting as a source of irritation, gives rise directly to such nervous phenomena. And in these cases the convulsions often do not end with the labour; they continue for some hours, perhaps days, until lengthening intervals and feebler attacks point to their gradual cessation. But they do not all end thus. Death may seize the patient even after the primary source of the excitation has, hours previously, been successfully terminated.

Case 2 was, as regarded the result, happily very different. It was a case of trismus some might say, but it was trismus arising in connexion with a notable injury to a nerve, and occurring as the first symptom of a general disorder. The lad was well housed, well clothed, and well nursed, so that any suspicion of exposure to the exciting causes of muscular rheumatism was readily excluded. Moreover, the relief afforded by the operation was marked and unmistakable.

As regards the case of the table-maid, I make no assertion that it was one of true tetanus. Possibly it was one of those, such as are described by Swan, in connexion chiefly with nerve wounds inflicted during venesection, but it had a very suspicious resemblance to the cases beginning, as Follin characterises them, by "secondary traumatic spasm." That tetanus has two distinct modes of onset is pretty well established—the one by trismus, the other by traumatic spasm, and the leading symptoms of this case were not unlike those observed in one recorded by Mr. Morgan.[1] In that instance a boy received from his master a blow on the hand with a cane. Pain and spasm commenced in the injured part, the first true symptom being a gradual spasmodic contraction of the flexor muscles of the hand, by which the fingers were drawn into the palm. The cramp gradually extended, and the lad died. But, be my case what it might, the lesson it taught was not an unimportant one, that by simple nerve section we may at times relieve very distressing reflex symptoms. And in so fatal a malady as traumatic tetanus, rare as the recoveries have been even after the performance of neurectomy, they have, I again submit, been sufficiently numerous to encourage its performance in fitting cases. A serious proceeding it doubtless is to sever a nerve trunk, and so perhaps condemn certain parts beyond to hopeless inactivity, but experiments and experience have shown that nerve suture can be performed with every fair prospects of success, and that the earlier the date at which it is carried out after the nerve has been divided the greater is the hope of recovery. Weir Mitchell[2] has shown that primary union after division is, except in early young subjects, almost unknown, and that the [illegible] the occurrence is due to the fact that degenera- [illegible] manifest themselves with great rapidity in the [illegible] extremities. A week, however, usually elapses [illegible] set in, and it is some little time before they are fully developed. It seems, then, that if in the early days after division the parts are kept in a state of relaxation so as to avoid what is so marked in the cases of severed nerve trunks, their tendency to retraction, that within a limited time, say a month after its division, the cut nerve might be [illegible] dealt with successfully. This as regards one

[illegible], Holmes's Surgery, vol. 2, p. 314.
[illegible] Injuries of Nerves, p. 235.

trunk. When, however, as in some injuries, it becomes necessary to deal with a whole plexus, the importance of and the anxiety attending the procedure are largely added to. Tripier speaks without hesitation in the matter, and advocates, if need be, "true nervous amputation" of the limb, expressing further the belief that within six months all harm following it would be gone. This is too sanguine an estimate; and in cases where many large and important nerves would require division amputation is, I believe, preferable. That even this extreme measure is not often attended by success is well known, and the personal experience I have had of it in four cases has not been encouraging. True, in one where half the hand was removed five days after the symptoms of tetanus were developed, there was for twelve hours marked benefit, but the spasms returned, unmitigated in their severity, and the boy died. Curling, however, in his well-known brochure tabulates a number of cases treated by amputation, of which, if memory serve me aright, he states that seven recovered. Have we when considering the propriety of nerve-section any canons to guide us as to the cases best suited for it, as to the special trunk or trunks which should be divided, and as to the best method of dealing with them after their division?

In all cases of traumatic tetanus, especially when attended by breach of surface, careful inquiry and examination should be made as to the existence of pain at the point of injury, as to tenderness in the course of the nerve trunks leading to it, and as to the part in which the spasm commences. Doubtless in many cases beginning with trismus these points are overlooked, and I am of opinion that by more careful search they may not unfrequently be discovered.

Knowledge of anatomy, as regards nervous distribution, of the existence of pain, of the starting-point of the spasm, of marked tenderness in the line of the nerves, and of the presence of Wood's symptom, "the manifestation of pain in the wound at the moment that pressure is made upon one of the nerve trunks which terminate in it," will all guide us as to the nerve or nerves to be divided.

It is quite possible that, in certain circumstances, after the neurectomy has been completed it may be well to take means to prevent the occurrence of primary union, and this will be carried out in the safest way by the method of Malgaigne, the doubling back upon itself of the peripheral section. This can in no way render more difficult the future operation of suture. Of nerve stretching I have not ventured to speak, as I have had no experience of it in tetanus, and the records, so far as I have read them, of the measure of success attending it have not been very favourable. The successful case of Vernetil is well known, as is one recorded by Mr. Wheelhouse[3] of Leeds; but apart from these and one occurring in the practice of Prof. Railton of Madras, I know of no others. As between stretching a mass of important nerves like the brachial plexus in a disease in which spinal polarity is extraordinarily increased or amputating the limb, I should prefer the latter.

Carlisle.

THE COMPLETE DESTRUCTION OF DISSEMINATED PATCHES OF LUPUS VULGARIS BY A NEW DOUBLE-SCREW EXCAVATOR.

BY MALCOLM MORRIS, F.R.C.S., EDIN.,
SURGEON TO THE SKIN DEPARTMENT OF ST. MARY'S HOSPITAL.

IT is generally admitted that surgical treatment alone is successful in this obstinate malady. Those surgeons, however, who have practised either scraping, or scarification, or both, will have been disappointed to find small isolated tubercles reappearing in the substance of the scar, or in the margin of the original patch. The truth is these little tubercles are difficult to remove by scraping or scarification. Yet it is absolutely essential that they should be completely destroyed, as otherwise they will become centres for the spread of the disease. To accomplish this end it is necessary, first, that the instrument should be somewhat larger than the tubercle, so that when inserted it may firmly grip the surrounding tissue; secondly, that it should possess many lacerating edges, whereby the nodule may be

[3] Medical Times and Gazette, 1880, p. 716.

Digitized by Google

thoroughly ploughed up; and lastly, that it should be capable of rapidly penetrating to the bottom of the nodule. Finding it impossible to comply with these conditions with the ordinary scoop, I devised an instrument, which has been made with much skill for me by Messrs. Krohne and Sesemann of Duke-street, and which, I think, fairly meets all the requirements mentioned—that is to say, in its size and in the number of its edges it fulfils the first two essentials, and a few words will suffice to demonstrate its still greater advantage of rapid penetration. In a single-threaded screw of, say, six edges, it is clear that six complete turns of the instrument will be required in order to insert the cone to its full depth. Now, the speed of entry is known to be in direct proportion to the "pitch" or distance apart of the threads of the screw. My plan has therefore been to arrange the lacerating edges round the cone in the form of two spirals, parallel to each other, in technical language, a double-threaded screw. By this means, as the pitch of each spiral, considered separately, is double that of the single-

threaded screw, it is obvious that the cone can be inserted to its full depth with but three turns of the instrument, the net result being to reduce the duration of the operation, and therefore the sufferings of the patient, by fully one-half. In withdrawing the instrument the soft new growth is removed and the resulting scar is flat, pale, and satisfactory.

Montagu-square, W.

NOTES OF

THREE FATAL CASES OF HEAT FEVER ("HEAT APOPLEXY"), WITH REMARKS.

By J. ALEXANDER WILLIAMS, M.B., M.R.C.S.,
SURGEON TO H.B.M. AGENCY, ZANZIBAR, AND FORMERLY HOUSE-SURGEON AND HOUSE-PHYSICIAN TO THE LONDON AND ROYAL PORTSMOUTH HOSPITALS.

THESE cases have recently occurred in Zanzibar. They were all natives of the coast; two were members of a gang of eight prisoners who had been brought from Mombassa, a town on the mainland not far distant, to Zanzibar for their trial on charges of murder; the third was imprisoned for some local offence. They had been here only three days, and during this time were confined in the Sultan's prison or fort; and I may perhaps as well here premise that with the management of the Sultan's prisons I have nothing to do, and my attention was drawn to what occurred through the British Consul (Sir John Kirk) taking an interest in the welfare of some of these particular prisoners. The prisoners were placed in a room on the basement of the fort, where were also confined from seventy to eighty other prisoners. The place in which they were confined measured, roughly, 25 ft. to 30 ft. long, by 15 ft. in height and 15 ft. broad. Absolutely no means existed for ventilating or lighting the cell except by way of the door, which was kept constantly closed, while the walls and roof being of solid stone and lime, in the form of concrete, prevented all possible percolation of air. Here the prisoners took food, slept, and performed all the natural excretory functions; no latrines existed. On March 15th at 4 P.M. the temperature of Zanzibar, as noted by the Indian Government meteorologist, was as follows:—In the sun the black bulb registered 149° F.; in the shade the temperature was 89·4°, the barometer standing at 29·98. This day at about 3.30 P.M. I was requested by Sir John Kirk to inspect the body of one of the prisoners, who was reported to have died suddenly in prison, and report as to the cause of death. On my arrival I found two of the Mombassa gang (Cases 1 and 2) dead. The condition of the cell from which these bodies had to be removed was shocking, and almost surpasses description. The entire absence of any ventilation, the extreme heat, the overcrowding of the prisoners, the effluvium arising from their excretions and from the damp and dirty walls, had produced an atmosphere so foul and pestilential that it was difficult to understand how life could possibly be sustained by it. On arriving at the cell I made three attempts to enter, but succeeded only in penetrating a few yards; the intense heat and foul atmosphere were too much for me, and I was compelled to retire and have the bodies brought into the open air for examination. When the cell door was first opened a rush of steaming, superheated, and horribly smelling air escaped like steam from a heated boiler. It was so saturated with aqueous vapour as almost to equal in density the air of a London fog, and spectacles were at once dimmed and rendered useless by it. The heat of the cell was intense; estimating it roughly, I should say certainly not less than 115° to 120°, and probably much higher. The stench was exceedingly foul and horrible, an indescribable odour peculiar to the place, and unlike any I had previously experienced or conceived possible. Huddled together on the floor of this vile den were the unfortunate prisoners, their skins reeking with perspiration, and their parched lips crying out, "Magi! magi!" ("Water! water!"). Many of them were very ill and feverish, totally uncared-for, and barbarously treated by their Arab gaolers.

After inspecting the bodies and noting down the post-mortem appearances, which were those indicative of death from asphyxia, and having unavailingly remonstrated with the Arab governor, urging him at once to remove the remaining prisoners from the cell, I hastened to report what I had seen to the Consul-General, Sir John Kirk, who at once accompanied me to the fort. This time, however, we were refused admittance, and it was only after Sir John had procured a special order from the Sultan that we were allowed to enter. We then found that during my short absence the doors had again been closed on the wretched prisoners, and on being opened another inmate of the cell, Case 3, whose name and history seemed unknown to the gaolers, was brought out comatose, in a dying condition; the body temperature was 106°, and the pulse and respiration almost stopped. The veins of the neck, face, and eyes were intensely congested, the symptoms presented closely coinciding with those already observed in the bodies of the two previous cases. He was evidently suffering from heat fever ("heat apoplexy"), due to the excessive heat and foulness of the atmosphere of the den from which he had been removed. A few minutes' artificial respiration, aided by two drachms of brandy administered hypodermically, soon caused the pulse and respiration to increase in force, frequency, and regularity. As it was certain he would receive no help or attention from the Sultan's officials, Sir John Kirk ordered him to be removed to my house for treatment, and here at one time he was so far revived that hopes were entertained of his recovery; but a relapse occurring, he died exhausted by the severity of the shock to which he had been exposed.

The following is an account of these cases as they were presented to me:—

CASE 1.—A man aged about thirty. When seen at 4 P.M. he had probably been dead from two to three hours. He appeared to have been taken ill about 1.30 P.M., when his comrades say he cried out and fell on the prison floor, foaming at the mouth. His arms and legs were seen to twitch violently for a short period; but soon ceasing, he lay quietly on the floor, so that he was thought to be asleep. A comrade examined him about 3 P.M., and found him dead; notice being given at the consulate, I was sent to examine the body. When the body was removed from the cell it was noticed that urine and fæces had been passed before death, probably during the convulsive seizure. There were no marks of external violence anywhere apparent, but there was intense venous congestion of the conjunctivæ, lips, and gums. The cervical veins were also engorged and distended, and a frothy foam escaped from the mouth. The body temperature was 107°. Rigor mortis had commenced in the lower jaw only.

CASE 2.—A man aged about thirty. When seen at 4.15 P.M. he had probably been dead about one hour. He appeared to have been ailing in the cell for some hours, and had complained of feeling ill to his fellow prisoners, who were said to have reported the fact to the gaoler, but no steps appear to have been taken in the matter till I arrived to examine the dead body of Case 1. Then this prisoner was reported t me as being very ill; he was at once re-

Digitized by Google

moved from the cell, and was then seen to be dead also. The natural appearances of the body were in all respects similar to those noted in Case 1, excepting that fæces and urine did not appear to have been voided. Thus there was intense lividity of the mucous membranes of the eyes, mouth, and lips; the cervical veins were turgid and distended; the lower jaw was wide open, and a frothy foam issued from the mouth; the pupils were contracted. Rigor mortis had not yet set in. Temperature of the body in the axilla was 107°. There were no external marks of violence anywhere apparent.

CASE 3.—A man aged about twenty-five was brought from the prison cell about 5.15 P.M., on my second visit to the prison, in a dying condition, having been seized with his illness in the interval which elapsed between my first and second visits to the cell. When brought out he was comatose; the pupils were contracted; frothy saliva was issuing from the mouth; the veins of the eyes, lips, mouth, and neck were intensely congested and engorged; pulse about 140, very small and flickering; respiration had almost ceased. He lay where he was placed like a log, perfectly motionless. Cold water dashed on face, chest, and abdomen, combined with artificial respiration, for a few minutes improved the respiration and lessened the lividity of the face and neck, and two drachms of brandy administered hypodermically soon caused a marked improvement in the pulse. The temperature in the axilla registered 106°. As it was certain he would receive no help or attention from the Sultan's officials, and there being no other place, Sir John Kirk ordered him to be at once carried to my house for treatment. When placed in bed a large ice-bag was applied to the head and back of the neck, and about half a pint of strong beef-tea with two ounces of brandy was introduced by the nasal tube into the stomach, where it was retained. At 7 P.M. the temperature still registered 106°; the pulse had increased in volume and was less quick. The lungs were perfectly clear and healthy. The nasal tube was again passed, and half an ounce more beef-tea, with twenty grains of quinine and two minims of croton oil, was administered; this also was retained. Ice was kept continuously applied to the head. As he lay on his back in bed, the eyes wide open and the pupils contracted, occasional slight twitching of the lips and arms were noticed; these extended to other parts, and increased in severity, so that at 1 P.M., when I was called up to see him, he was in a general epileptiform convulsion, and jerking the body so violently that it was difficult to keep him in bed. The eyes were wide open, and the globes jerked convulsively upwards and to the right; frothy saliva was issuing from the lips. The bowels had been opened, with copious watery evacuations, and the bladder emptied. The temperature in the axilla was 103°. Chloroform was cautiously administered, so as to produce complete anæsthesia, which was maintained for about fifteen minutes; this had the desired effect of completely arresting the convulsions, which did not return, only a few faint twitchings of the fingers, lips, and eyes being subsequently noticed. During the remainder of the night and next day he lay comatose and motionless in bed, breathing comfortably, the chief cause for anxiety being the exceedingly feeble action of the heart.—March 17th: During the day he lay in bed on his back, motionless; bowels opened thrice, and urine voided naturally. The pulse was still very feeble, but had improved in force and volume somewhat since the previous day. Temperature at 10 P.M. 102°; still fed by tube every four hours. Five grains of quinine were administered at night.—18th: Temperature at 10 A.M. 102°. He appeared weaker, although at times he seemed semi-conscious, and partially opened his mouth when the stomach tube was passed. At 4 P.M. the temperature was 104·4°; at 7 P.M. it was 105°; pulse very feeble; lungs healthy; skin hot and dry; tongue parched. Twenty grains of quinine were administered, with beef-tea and three ounces of brandy. At 11 P.M. the temperature was 106·2°. During the night the pulse became weaker and weaker, and he gradually sank, and died quietly at 3 A.M., the temperature in axilla after death being 106°.

Necropsy, four hours after death.—The head was first examined, and on removing the skull-cap, the venous sinuses of the brain and its membranes were seen to be intensely congested and engorged with fluid venous blood. The ventricles contained a few ounces of serum, but not in excess; no other pathological change was noted in the brain. The heart, left ventricle, was firmly contracted and empty; the right side and the large veins were distended with dark fluid blood, which, on escaping from the vessels, coagulated into a soft dark clot. The lungs were perfectly healthy, but very little congested. The kidneys were small, pale, and healthy. The spleen was small, dark in colour, normal. The liver and intestines were healthy. The muscles were well developed and of dark colour, and the body was healthy and well formed in all respects. Rigor mortis had set in in the lower jaw and arms only. Putrefaction had not commenced.

Remarks.—One of the most important and interesting features presented by these cases arose in connexion with the determination of the cause of death. Inspection of the bodies of Cases 1 and 2 afforded strong evidence that the ultimate cause of death had been asphyxia. In what way had this been induced? The fact that the patients were all members of the Mombassa gang, and had been in the prison only two or three days, raised a suspicion of foul play; but this was negatived by the absence of marks of violence on the bodies, by the testimony of their fellow prisoners, and by the absence of any history of a quarrel. The mode of onset of illness in Case 1 suggested death during an epileptic seizure, and with this the appearance of the body was quite consistent. A striking feature noticed on examining the bodies of Cases 1 and 2 was the excessively high body temperature, 107° being observed in each case; and this directed attention to the nervous system as being the one primarily at fault, for in cases of nerve lesion it is common to find a high post-mortem temperature, which, on the other hand, would be necessarily rare in cases of simple asphyxia. After seeing Case 3 the diagnosis at once became apparent, for in this case there could be no doubt that he was suffering from the effects of excessive heat, "heat apoplexy," producing complete coma and great depression of the cardiac and pulmonary functions. The term "heat apoplexy," as applied to such cases, is derived from the resemblance which the sudden onset and completeness of the coma bear to cases of ordinary apoplexy dependent upon diseased vessels. From it, however, it may readily be distinguished by the symmetry of the symptoms. The muscular paralysis is complete and general, not unilateral or localised to certain groups of muscles, as is common in ordinary apoplexies. Again, the pathology of the two diseases is entirely different, for although it is popularly believed that the symptoms of heat apoplexies are produced from an intense venous engorgement of the brain and its membranes, leading to an effusion of serum into the ventricles and meninges, yet this is not supported by the accounts of the post-mortem examinations of these cases; for, as a rule, as in Case 3, nothing beyond slight cerebral congestion can be found, the cerebral fluid is not in excess, nor are there any signs of pressure having been exerted on the brain. A more rational pathology is that at present taught in most hospital schools, that the symptoms result from the circulation of the over-heated blood through the cerebral vessels; as a result profound disturbances are set up in the nerve centres, and reflected thence to the vaso-motor nerves of the body generally, leading to increased production and retention of heat and hyperpyrexia. The changes thus induced in the nerve centres, and especially the respiratory, are at first those resulting from over-stimulation, rapidly followed by those indicative of exhaustion. The local and atmospheric conditions by which these prisoners were surrounded were exceedingly favourable for the development of heat fever. It is a well-known fact that in a dry atmosphere, where free evaporation and radiation of heat from the surface of the body are possible, the human body can bear with impunity very high degrees of heat, and the body temperature remains constant. If, however, radiation and evaporation be prevented by deficiency of ventilation, or by excess of moisture in the atmosphere, then exposure to a temperature but a few degrees above the normal will rapidly prove fatal, and a high body temperature will be developed. A point I have hitherto purposely avoided now comes for consideration: Were these the only fatal cases that occurred? Upon this point I have no positive information. With these cases alone I was concerned; but, judging from the miserable condition of those I saw in the cell and the filthy condition of the den in which they were incarcerated, I am inclined to think not; and the result of Sir John Kirk's inquiries consequent upon these disclosures as to the fearful state of the Sultan's prisons goes to show that deaths had been of daily occurrence, of which no notice was taken; and also that small-pox is endemic in the fort. The people, when removing these bodies, appeared

Digitized by Google

to be performing no unfamiliar task. Many prisoners in the cell looked extremely ill, but, being entirely under Arab jurisdiction, they might die or not without Europeans becoming acquainted with the fact. The strong representations made to the Sultan by Sir John Kirk immediately he became cognisant of the facts were so far successful that this and other dens of a like description were cleared the same evening, and orders were given to have windows placed in them for ventilating purposes. Such a remedy, however, can only be palliative. The cells are incapable of proper ventilation, and the only real and effective remedy to prevent the recurrence of such scandalous barbarities is to have the fort demolished and a proper prison built in its stead. This has been strongly but unavailingly urged upon the Sultan, and nothing short of a strong expression of public opinion, combined with firm diplomatic pressure, can avail to prevent the possibility of the constant recurrence of such horrible tragedies.

Zanzibar.

CASES OF SUNSTROKE WITH HIGH BODILY TEMPERATURE.

By T. F. O'DWYER, M.D.,
SURGEON MAJOR, ARMY MEDICAL DEPARTMENT.

CASE 1.—Private W. T—— (Highlanders), walked to hospital on July 29th; he complained of dizziness in his head. His skin felt very hot; the pulse was quick and weak. He was stripped to the waist, and buckets of cold water were dashed over his head and back. He said he felt much better, and laughed at the idea of being carried upstairs on a stretcher. Before he arrived at the ward, however, he became insensible. His breathing was oppressed; carotids throbbed visibly; pulse weak and quick; pupils contracted; temperature, carefully taken in axilla, 110° F. He was at once stripped and placed in a bath, to which large pieces of ice had been added. An icebag was placed on his head and a large piece of ice was held to his neck and back of the head. A lump of ice was placed in his mouth to melt. After being ten minutes in the bath he became conscious and looked about him, but his pulse was very weak and flickering. A draught of aromatic spirits of ammonia was now administered. He was removed from the bath, when his temperature was found to be 105°. He became unconscious, and the temperature began to rise. He was again put into the cold bath, and in ten minutes the temperature of the body fell to 99·5°, and he became conscious. He was removed from the bath and an enema of sulphate of magnesia (B.P.) was administered cold. The temperature did not again rise and he made a rapid recovery, but remained weak and suffered from headache for some days.

CASE 2.—Private B——, (Highlanders) was brought to hospital on July 28th, 1883, in a state of insensibility. Pupils contracted; breathing oppressed; pulse feeble and rapid; temperature 109° in axilla. He was treated as in Case 1, but his pulse became so feeble after removal from the bath that fifteen minims of sulphuric ether were administered hypodermically, and he revived at once. Temperature fell after the bath to 100·6°, and did not rise afterwards. He made a quick recovery.

CASE 3.—Private —— (Highlanders), employed in the regimental transport and much exposed to the sun, was brought to hospital on July 28th, insensible. Temperature in axilla 108°; pupils contracted; heart's action weak. This patient was treated as Cases 1 and 2. Temperature reduced to 101° by the cold bath, after which his pulse was so weak that he required half an ounce of brandy and two drachms of aromatic spirit of ammonia, repeated at short intervals for three doses. He made a good recovery. These cases are typical of some that took place about the same time, and are remarkable for the high bodily temperature, the feeble condition of the heart from the same cause, and the satisfactory termination in every instance, as we were able to deal with them at once. All took place at a time when the sun's rays were very powerful, and when cholera prevailed at Cairo.

Citadel Station Hospital, Cairo, Aug. 1883.

THE annual prize festival in connexion with the Royal Normal College for the Blind, Upper Norwood, was held at the Crystal Palace on the 19th inst.

LITHOTRITY AFTER BIGELOW'S METHOD.

By C. R. GRAHAM, L.R.C.P. ED., M.R.C.S.,
HON. MEDICAL OFFICER, ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

MR. C——, aged sixty-two, an architect, of active and temperate habits, came under my care in private, in October, 1883. Eight years ago he passed a large quantity of minute calculi, some of the largest being about the size of a small pea. Ever since he has been troubled with frequent micturition, pain in the penis, and retention, having occasionally to seek relief from catheterisation. It was on account of this last symptom that I was at first summoned. At a subsequent examination I sounded him, detected several calculi, and also found that the prostate was enlarged, particularly the middle lobe, the sound winding to the left side immediately before passing into the bladder. This caused a little difficulty in passing the lithotrite. The urine contained a small quantity of albumen, and there was an abundant deposit of muco-pus. Operation was recommended, but the patient delayed it on account of some business engagements. In the meantime, however, he had several attacks of cystitis, causing him intense suffering and preventing sleep. His general health began to fail, and in December he was only too glad to seek relief. For a fortnight before the operation I kept the patient in-doors, and for a week prior, finding that there was a certain amount of residual urine, I passed a catheter daily. This treatment produced a marked improvement in his condition. Three days before operation the patient was confined to bed. On Dec. 20th the operation was performed; it lasted an hour and a quarter. The largest calculus was about the size of an almond. A medium-sized, non-fenestrated lithotrite was used, a No. 16 evacuator. CbC'_3 was at first administered, and anæsthesia was kept up with ether. After the operation there was no reaction, and the patient suffered very little pain. About an ounce of bloody urine was passed every hour for the first day; this gradually became clear, and micturition less frequent. On the second day after operation the urine became purulent, and the bladder was washed out daily for a week, at first with a weak solution of boracic acid, afterwards of nitric acid. The urine was especially bad on the third day, and an ounce of the decoction of couchgrass was ordered every four hours. A small quantity of detritus came away the first few days, when the bladder was injected. On the eighth day there was no pus in the urine, and the quantity passed in twenty-four hours varied from two to four pints. After this time he was practically well. He got up on the thirteenth day. With regard to diet, the first week it consisted of milk and barley water, after which he took solid food. Owing to the enlarged prostate I directed him to pass a catheter daily so that the bladder might be properly emptied, and this he continues to do. He is now, four months after the operation, in perfect health, has gained flesh, and follows his usual work. The detritus weighed between four and five drachms. The stones consisted of phosphates, with small uric acid nuclei about the size of a lentil. Of these there were four.

GUY'S HOSPITAL.

CASE OF CONICAL CORNEA OF BOTH EYES.

(Under the care of Mr. C. HIGGENS.)

FOR the following notes we are indebted to Mr. C. Y. Shuter, dresser in the eye wards:—

Caroline J——, aged eighteen, was admitted on March 3rd, 1884. Three years ago she first noticed that her sight was failing, both for near and distant objects; the vision got gradually worse up to the time of admission.

On admission there was well-marked conical cornea in

Digitized by Google

both eyes, the right being the worse. The right eye could not read any letters with or without a lens; the left eye could read large type (Jaeger 19) at ten inches. On the day of admission (the pupil being well contracted by eserine, which had been used for two days previously), the patient having been anæsthetised, a small elliptical portion of the right cornea, including the whole thickness, was excised from the apex of the cone; the eyelids of both eyes were closed by strapping and covered with a wet pad and bandage.

On March 10th, or one week after the operation, the eye was examined for the first time; the wound had healed, and the pupil was circular.

On April 28th the left eye was operated on and treated in the same manner as the right. A week later the aqueous was retained, and the pupil was circular.

On May 12th the wound had probably reopened, and an anterior synechia had formed; a four-grain solution of sulphate of atropine was ordered to be used three times a day, in the hope that its action might detach the adhesion. On the 16th the adhesion had stretched, but had not given way; atropine was then used six times a day.

On June 6th, the atropine having had no further effect upon the anterior synechia, it was discontinued. In each eye there was a small central corneal opacity, together with the synechia in the left. The right cornea was still rather conical, the curvature in the left to the naked eye looked about normal. The left eye could read Jaeger No. 2 at twelve inches, and had vision for distance = $\frac{6}{24}$, without assistance. The right eye could read Jaeger No. 16 at eight inches, and had vision for distance = $\frac{6}{36}$. It was not improved by lenses.

YORK COUNTY HOSPITAL.

SIX CASES OF EXCISION OF THE KNEE-JOINT.

(Under the care of Mr. JALLAND.)

FOR the following notes we are indebted to Mr. A. Jefferson, house-surgeon.

CASE 1. *Synovitis following a Fall; Abscess; Rest in bed for eighteen months; Excision; Recovery with good Limb.*—J. M——, a boy aged eight. The parents stated that when he was four years old he fell and injured his knee. The joint was not at once very painful, but a few weeks after the accident it began to swell and to be very tender. Gradually it got worse, the boy being confined to bed. At length an abscess opened at the inner side of the joint, and after discharging for some months it healed up. The swelling of the joint and the concomitant pain had by this time disappeared, and he was able to get up and move about on crutches, having been confined to bed about eighteen months. There was now much deformity on the affected side, and the child had to use the crutches always. On admission he walked with his diseased limb twisted round the back of his crutch, the knee being drawn up on the inner side and the foot twisting round to the outer, the toes being about three inches off the ground. The muscles on this side were somewhat atrophied, the tibia was dislocated backwards and rotated inwards, and there was a large cicatrix at the inner and back part of the joint, with slight movement. The patient being fairly healthy, the knee was excised on March 14th, with antiseptic precautions. The limb having been exsanguinated and a tourniquet applied, the usual semilunar incision in front of the joint was made; the patella, being firmly adherent to the anterior surface of the lower end of the femur, was treated as part of that bone. Before the limb could be got straight half an inch of bone had to be removed from the lower end of the femur and the same amount from the tibia. The pieces were taken away wedge-wise, with the base of the wedge forward, the cut surfaces were brought in apposition, and the straight limb was placed on a back-splint, interrupted at the knee-joint by a large quadrilateral iron bracket, sufficiently broad transversely to allow of a thick bandage being passed between it and the knee. This splint was provided with a foot-piece, and it extended as high as the gluteal fold; the padding of it, except the foot-piece, was covered with a strip of carbolised bees-wax bandage. Similar bandaging was employed in the turns taken round the limb and splint immediately above and below the excised joint, the rest of the bandaging being done with plaster-of-Paris bandages, which were continued on as a spica round the pelvis, and strengthened opposite the hip-joint with strips of saturated house-flannel. A pad of salicylic silk, with the usual gauze dressing, was applied to the wound. On the day after the operation the wound was dressed. On the evening of the same day the temperature was 100·4°. On the following day the evening temperature was 99·8°. After this at no time did the temperature rise higher than 99·6°. A week after the operation the wound was again dressed; there was scarcely a trace of pus, and the drainage-tube was removed. The next dressing was applied three weeks after the operation, when the wound was found to be quite healed and firm, except at its extremities. Finally, four weeks after the operation the antiseptics were discontinued, and the limb was taken for the first time off the splint, being apparently quite firm to moderate pressure. It was put up in plaster from above the ankle upwards, round the pelvis, a "window" being left over the wound. On the following day the patient got up, having been in bed exactly four weeks. For two weeks this plaster splint was kept on; it was then removed, and the joint found to be quite firm. A short plaster splint, extending a few inches above and below the joint, was then applied and the patient, being provided with a thick-soled boot, was allowed to put a little pressure on his leg. In another week he left the hospital and returned home. At the end of a month the boy presented himself for inspection; he could then put all his weight on the leg and walk about the house without his crutches. The splint was now taken off, and his father was told to at once bring him to the hospital should any pain in the wound return. Some months afterwards, a patient living in the same village as the boy stated that he was running about "like the rest."

CASE 2. *Chronic Synovitis; Persistent Pyrexia and Emaciation; Excision; Rapid Subsidence of Constitutional Symptoms, and Recovery with good Limb.*—M. F——, a female aged twenty-two. The patient had been under observation at the hospital about six months. When first seen her left knee-joint was slightly flexed and swollen, and was evidently in a somewhat early stage of femoral fungous synovitis. Under ether the joint was straightened and put up in plaster. The pain having subsided, she was sent home, under strict injunctions not to put her foot to the ground. Finally she went to the seaside, and there took her splint off. Although not putting her foot to the ground, the pain gradually returned in all its acuteness, the swelling increased, and she again applied at the hospital nine months from the time she was first seen. On admission she was much exhausted and emaciated, having had constant pain and sleepless nights. The condition of the joint was serious; it was much swollen, exceedingly hot, tender, and painful, with frequent jumping, which rendered sleep impossible. There was also pyrexia, her temperature rising three and sometimes four degrees above normal at night. She had also prolonged expiration and occasional rhonchus at the right apex. After about a fortnight's treatment, the joint was excised on July 18th, 1882. The operation was performed in exactly the same way as the preceding, except that the patella was removed; the cartilage on the outer condyle of the femur and tibia was much eroded. A similar splint and dressing was applied as in the preceding case. On the following day the patient expressed herself as feeling much relieved. She had had a good night, and there was very little pain in the wound; a little blood having oozed out, it was dressed. In the evening the temperature was 100·4°. For the next eight days the wound was dressed daily. For seven days after the operation the evening temperature ranged from 100·4° to 101·6°, being only a little above normal in the mornings; afterwards the temperature never rose above 99·2°. On the fourteenth day the wound was again dressed and the drainage-tube removed; it was now left until the thirty-fourth day after the operation, when it was again dressed, and found to be quite healed, except at one extremity. On the forty-first day the antiseptic dressing was discontinued; the limb was taken off its splint for the first time and put up in plaster as in the preceding case. On the following day the patient returned to her crutches, it being exactly six weeks after the operation. Being much improved in general health she now got on rapidly. At the expiration of eight weeks the plaster was taken off and a short gutta-percha splint applied. The wound was quite firm and she was sent to the seaside. For two months longer she wore a laced-up splint. At the end of this time she could walk quite well without any support; it was now four months since the operation. When last seen she had left off her splint and was working at a confectioner's.

CASE 3. *Acute Fungous Synovitis; Great Pain in Joint; Pyrexia and Lung Symptoms; Excision; Recovery with good Limb.*—M. S——, a female aged twenty-four, pre-

Digitized by Google

sented herself in May, 1882, suffering from intense pain in the right knee-joint, which had commenced to be painful and then to swell six weeks before. The pain and jumping in the joint prevented sleep. She had been in bed for three weeks. On examination she was found to have a much enlarged and exceedingly tender joint, evidently the seat of a fungous synovitis. There was considerable pyrexia; a temperature of over 99° in the morning and between 101·5° and 102·5° in the evening. For a fortnight after her admission, notwithstanding the local application of ice with rest and general treatment, the temperature continued high; it then began to subside, and for the following month remained fairly normal, with only occasional nocturnal jumps. The pain, however, remained constant and the fungous proliferation increased; at the same time crepitation appeared at the apex of the left lung, together with night-sweats, both of which were absent on her admission. Under these circumstances it was resolved to excise the joint. This was done on June 13th, 1882, in a manner similar to that in the last case. There was on the external tuberosity of the tibia a portion of cartilage, eroded, the size of a two-shilling piece. On the day after the operation the wound was dressed; the patient expressed herself as feeling less pain than before; in the evening her temperature was 100°. Henceforth only on three occasions did it rise above 99°, and of these three the highest temperature was 100·2° only. The wound was again dressed on the following day; it was then left until the ninth day after the operation, when it was dressed and the drainage-tube taken out; the next dressing was applied on the twenty-first day after the operation, the wound, except, at the two extremities, being healed. Finally, twenty-seven days after the excision the antiseptics were discontinued, the limb, for the first time, taken off the splint and a plaster splint applied, as in the preceding cases. The next day she got up and moved about on crutches, it being exactly four weeks since the operation. The further progress of the case was almost the same as in the preceding. The patient is now earning her own living, her lung symptoms having quite disappeared.

CASE 4. *Chronic Synovitis; Joint opened, and Fungating Synovial Membrane removed; Persistence of Symptoms; Excision; Suppuration of Wound; ultimate Recovery with good Limb.*—S. M——, a female aged fourteen, was admitted early in March, 1882. She had a bad family history. Her present illness had commenced three years ago with pain and swelling in the right knee-joint. On examination this joint was found to be much swollen and very tender. She had great pain in it, much aggravated for the last three months, during which time she had emaciated somewhat. There was no jumping of the joint. The patient's nocturnal temperature varied from 101° to 102°. After she had been under treatment about a week the pain had increased, as also had the swelling; the skin over the joint, too, became red, and mixed with the boggy semi-fluctuation of the proliferant synovial membrane appeared some true fluid fluctuation. It was resolved to open the joint to examine it and let the fluid out; accordingly, on March 21st, two longitudinal incisions were made, one on each side of the joint, and so placed that they could, if necessary, be run one into the other, as an excision flap. Through these incisions about half an ounce of pus escaped. The cartilages being apparently sound, as much of the fungous membrane was taken away as could be got at, and the joint was thoroughly syringed out; the limb was then put up in a similar way as in the former cases. The temperature still remained as high as before, and the joint after a few days began to jump. As the pain got worse, excision was performed under the carbolised spray three weeks after the joint had been opened. There was found to be a good deal of erosion of cartilage and a very large quantity of fungous membrane, which was sliced off. The limb was put up as before. On the following day the patient said she had less pain; the evening temperature was 101·8°. After this only once was 101° exceeded. For the next eight days the wound was dressed every other day; the discharge then increased and the dressings were applied daily. Finally, eighteen days after the operation, the wound was no longer aseptic. Pus also had run up the splint; a fresh one was therefore put on, ether being given. From this time the discharge continued with great profusion, a counter-opening having to be made into the popliteal space. The wound healed but slowly, there being many obstinate sinuses in the course of the line of incision. Gradually, however, firmness was acquired and the discharge lessened, syringing with dilute red wash and the application of a Martin's bandage outside the ordinary dressings being employed; the splint had to be frequently changed. About four months after the operation there was considerable firmness of the bones. The discharge from the popliteal opening continuing, and the sinuses in front not being healed, a plaster splint could not be applied, so the patient was kept in bed. It was not until six months after the operation that the popliteal sinus closed; the limb was now put up in plaster, the wound being syringed and dressed through a window in the splint, the patient being allowed to get about on crutches. In the following spring she went to the seaside, a year having elapsed since the operation. On her return at the end of a month she could bear a certain amount of weight on the foot, the sinuses now discharged but little. The long splint was taken off and a short, laced-up, gutta-percha one applied. Finally, fifteen months after the operation she could walk; she was then at a charity school and her sinuses were still discharging, though but little. Since then she had been heard of and was said to be walking about quite well.

CASE 5. *Synovitis following a Fall; Excision; Vomiting; Albuminuria; Coma; Death; Acute Nephritis.*—T. W——, a male aged three, was brought to the hospital in Nov. 1882. His right knee-joint had been swollen and painful for six months. His family history was good, and the joint affection was apparently the result of a fall. On admission the child was found to be suffering from fungous synovitis of the joint; he was evidently suffering much pain, and his sleep was greatly disturbed by jumping of the limb. Extension was applied, together with ice, &c., but his condition did not improve; his temperature remained high, and he got thinner. After a month's treatment, his symptoms being worse, excision was performed on Dec. 6th, 1882. The tibial cartilages were much eroded. The operation was carried out as in the preceding cases, and the dressings, &c., were the same. On the day after the operation the patient volunteered the statement that he was much better. The wound was then dressed. The evening temperature was 100·4°. Seven days after the operation the wound was again dressed, for the purpose of getting out the drainage-tube; there was found to be scarcely any pus. On the eleventh day after the operation the evening temperature was 102·6°, the highest previous temperature being 100·4°. On the following day the wound was dressed; it appeared quite healthy, and was healing well, there being but very little discharge on the dressings; in the evening the temperature was normal. On the two succeeding nights the temperature was also normal. It then rose again, and on the fifteenth and sixteenth nights after the operation it reached 101·8° and 102·4° respectively. No cause for this rise could be detected; the child did not complain of any pain in the wound—indeed, ever since the operation he had had comparatively no pain in it. For the next six days the evening temperature was lower, 100·4° being the highest, but the child was looking pale, although he complained of nothing. The wound was now dressed for the fourth time after the operation; it had healed nearly entirely, and the cicatrix was firm; the excised part could be moved laterally on the splint without giving rise to pain. On the evening of this day, the twenty-third after the operation, his temperature was 101°, and he began to vomit; his urine contained albumen, but no blood or carbolic; the vomiting continued, notwithstanding treatment, and on the twenty-fifth night after the operation his temperature was 102·6°. For two more days the vomiting and temperature persisted, and the amount of albumen in the urine increased up to nearly one-half; there was a trace of blood, but never any carbolic. Finally, on the twenty-eighth day after the operation, his temperature became subnormal, 97·2°; he was semi-comatose, and early on the following morning he had a convulsion and died. A post-mortem examination could not be obtained, but it appears evident that the child died of acute nephritis, probably induced by chill at the time of one of the dressings (before the operation there was no trace of any albumen in the urine), and evidently increased at the time of the last dressing. It is impossible to say when the disease really started, as the child complained of no subjective symptoms until the nausea began, and the urine was not examined for three weeks—viz., from before the operation until the evening after the last dressing.

CASE 6. *Chronic Synovitis following a Blow with a Cricket-Ball; Excision and Suppuration of Joint; Amputation eight months after Excision; Recovery.*—E. B——, male

Digitized by Google

aged thirty-four, came to the hospital in May, 1882. As in the preceding cases, his knee was the seat of a fungous synovitis, the left joint being the affected one. The previous history of the disease was that eight years before his admission he had been struck on the left knee by a cricket-ball. For a few days after there were swelling, pain, and lameness. These symptoms recurred during the ensuing six years with more or less frequency, there being intervals in which there was entire cessation of pain and entire disappearance of the swelling. Two years before his coming to the hospital, however, the joint appeared to get worse; it became swollen and the swelling persisted. The pain also increased, and for the last six months had been almost continuous. On admission there was much pulpy swelling of the joint, together with grating, as of eroded cartilages. Having had the patient under observation about two weeks, in which period pain, pyrexia, and sleeplessness were constant, it was resolved, the patient's lungs and kidneys being apparently healthy, to perform excision. This was done on June 20th. A good thickness of bone had to be removed, the cartilage, being completely absorbed and much of the underlying bone carious. The operation, &c. was conducted in the same manner as in the preceding cases. For a few days after the excision had been performed the patient expressed himself as being much improved; his nocturnal temperatures were, however, high—102° to 103°—and the wound had to be dressed daily, there being at first a good deal of hæmorrhagic oozing and afterwards much pus. At the end of about ten days the patient began to have a good deal of pain, which necessitated the hypodermic use of morphia; the discharge further increased, and at the end of the third week the wound was no longer aseptic. The splint was now changed, ether being administered, and was replaced by a fresh one. The wound, which had healed in front, was dressed with carbolic water dressing. In about another three weeks the discharge had lessened and a fairly firm cicatrix had formed, intersected, however, by numerous sinuses. The splint was now again changed, and a thick bees wax apparatus adjusted. This was done under ether, and the joint appeared fairly firm. The wound was now dressed with red wash, the sinuses irrigated with weak carbolised red wash, and elastic pressure kept up by means of a Martin's bandage over the dressings. The patient now began to improve. His morning temperatures were always normal, and his evening temperature only one or two degrees above normal. At the end of the eleventh week he had so far improved, and the discharge had so much lessened, that his splint was taken off and a plaster one applied from above his ankle below to his pelvis above, a window being cut over the wound. This was done without anæsthesia, and, so far as it was deemed expedient to test, the union of the bones was perfect. In his plaster splint the patient expressed himself as being much more comfortable, and after he had had it on for a week he was moved from his bed to a couch in the ward; and, this causing him no pain, after a few days he was allowed to get about on crutches. After walking about some ten days he received a jar in the affected limb from the slipping of his crutch, and at once there was a return of the former pain. He was again confined to his bed, his evening temperature once more rose to two or three degrees above normal, and an increase in the discharge took place. Henceforth he remained in bed, suffering at times much pain; occasionally the discharge decreased, the sinuses appeared to be healing up, and the pain and pyrexia almost left him, but these hopeful symptoms never lasted more than a week or ten days together. At length, eight months after the excision, the patient himself wishing to get rid of the limb, and there being apparently no hope of its ever being of any use to him, Mr. Jalland amputated through the thigh. On examining the excised ends of the bone they were found to be united together by ossified patches, while between these patches wandered carious discharging sinuses; what adhesions there were were not firm, but broke down readily under the handle of the scalpel; and on the exertion of only a slight amount of force, the soft parts being cut through, the ends of the bones were bent apart. After the amputation the patient made an excellent recovery, and soon returned to his work as a carpet-maker.

Remarks.—The above cases show that if, in the treatment of excised knees, almost absolute rest be given to the wound, healing will be rapid and the patient able to leave his bed at the end of a few weeks. In all the six patients the affected limb was put on the splint with plaster spica, as described in the case of J. M—— (Case 1). It will be noticed that only in the two patients, S. M—— (Case 4), and E. B—— (Case 6), was it necessary to change this splint, the close packing of salicylic wool saturated with carbolised wax between the limb and the splint, together with the waxed bandages, effectually prevented the discharges on the one hand from running up or down the leg, and on the other from soaking into the splint, the waxed surface at once turning off the fluids into the dressings. The number of antiseptic dressings applied is also noteworthy. In the first case only three dressings were put on; in the second the wound was dressed daily for eight days, after which it was only dressed twice; in the third it was only necessary to renew the dressings four times; and in the fifth the wound was dressed four times in twenty-eight days, at the end of which time the patient died. This infrequency of dressing was, no doubt, in great measure due to the absorbent salicylic silk used as a thickish pad next the wound. In the two remaining cases, Cases 4 and 6, dressings were applied almost daily for eighteen and twenty-one days respectively, after which their wounds became septic. In Case 4 the joint had contained pus, and had been washed out three weeks before it was excised. The antiseptics were therefore much handicapped. Practically, failure to keep the wound aseptic may be said only to have occurred in Case 6. With regard to the times of application of these dressings, it may be remarked that they were not renewed on each occurrence of oozing; such a procedure by which a wound may be disturbed many times in the twenty-four hours, not only causes much pain to the patient, but seems to be disregardful of the great principle of rest in the treatment of wounds. Instead, therefore, of each appearance of discharge through the dressings being followed by a change of dressings, the area of penetrating fluid was immediately covered with a pad of salicylic silk bound on with a gauze bandage. The splints not having to be taken off and the wounds not being disturbed often by change of dressings in each of the first three cases recorded, healing took place, and the patients were able to leave their beds and go about on crutches, four weeks, six weeks, and four weeks respectively, after the operation. In some of the patients the temperature was lower after the operation than before, and in most the pain was afterwards decidedly less, although excision should never be performed until a very patient trial has been given to perfect rest in acute cases, or in exacerbations in the form of rest on a back splint, with the addition of the local application of ice; in more chronic conditions (the joint having been, if necessary, straightened) in the shape of plaster-of-Paris splint, with crutches and a sling for the leg. Still, should the disease persist in being aggressive, and the consequent exhaustion, with its tendency to phthisis and its receptivity to tubercle, ensue, one should not hesitate to excise, for there appears to be every reason for us to regard the result of such excision hopefully. In two of the cases the chest symptoms entirely disappeared after excision.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of the above Society was held on Wednesday, July 2nd, Dr. Henry Gervis, President, in the chair.

The following specimens were shown:—Phosphatic Calculus which caused a Vesico-vaginal Fistula, by Dr. Godson; Transfusion Apparatus, by Dr. Walter (Manchester); Double Uterus with Single Cervix, and a deciduous substance expelled after labour for the fifth time, by Dr. Cleveland; Pedunculated Fibroid removed from a Prolapsed Uterus, by Dr. William Duncan. A report of the committee on Dr. Neugebauer's specimens of Spondylolisthesis was read. The committee consider that the specimens bear out Dr. Neugebauer's views, which are essentially that the anterior half of the vertebra (typically the fifth lumbar) glides away from the posterior half owing to congenital deficiency or fracture. Such predisposing causes may not result in spondylolisthesis without the operation of overweighting. Dr. Neugebauer states that Professor Lambl has withdrawn his theory of hydrorachis as a cause of spondylolisthesis. Mr. Noble Smith's appendix to the report was read; he describes specimens showing caries as probably a consequence of displacement.

Digitized by Google

The following papers were read:—

On Fibro-cystic Myoma of Uterus—Septicæmia, by Dr. H. A. LEDIARD (Carlisle).—The symptoms dated twelve months back, and included pain, bleeding, vomiting, and anæmia. The tumour felt cystic in parts and a bruit was heard over it. It reached two inches and a half above the navel. Afterwards diarrhœa set in, and the temperature rose. After an examination by the sound severe symptoms began, including the usual signs of peritonitis, and death occurred on the ninth day. The tumour grew chiefly from the posterior wall, and was partly cystic, as were both ovaries. The kidneys contained miliary abscesses. The spleen was enlarged and soft, containing several recent infarcts. Liver fatty. Lungs œdematous and congested. No trace of peritonitis was found, but no examination of the veins was made. The uterine mucous membrane was nowhere abraded. The case was brought forward chiefly to ascertain the opinion of the Society as to the cause of death. —The PRESIDENT said that Dr. Lediard was not singular in his experience. A small abrasion was sometimes fatal.

Note on the Condition observed in the Navel Cord of a Young Infant, by Dr. JOHN WILLIAMS.—The cord at birth appeared natural. On the second day the distal two inches had dried, while the proximal inch was succulent as at birth. In the next few days it broke down and became stinking. There was some bleeding on the fifth day; the cord did not fall off till the ninth day, when it left a somewhat conical stump with an ash-grey surface and a small red central depression. A thin sheath sloughed off the stump. Sir J. Paget, who saw the child, advised its removal (if it remained) by ligature, as in the case of common wart of the umbilicus. It disappeared altogether on the fourteenth day. The early appearance of the wart was remarkable; it had not been observed before the eighth day.—Remarks were made by the PRESIDENT, Drs. EDIS, WILLIAMS, and HERMAN.

Note on the Involution of the Puerperal Uterus in the absence of the Ovaries, by Dr. JOHN WILLIAMS. — The patient had had her left ovary removed in 1879, and her right was removed during labour in 1883 for cystic disease. Recovery was uninterrupted. The involution was decidedly delayed, and on the twenty-eighth day it was still above the brim; the sound passed four inches. Seven weeks after delivery the uterus was of the size usual in the fourth week. Seven months after delivery it was smaller than the virgin organ, sharply anteflexed, and the cavity was only two inches long. In this case the immediate effect of removal of the ovaries was retardation of involution, but the changes in the peritoneum caused by ovariotomy must be remembered. The ultimate result was exaggeration of the uterine involution, like senile atrophy. The PRESIDENT endorsed Dr. Williams's view of the case.—Dr. CARTER remarked on the rarity of super-involution. There exists, without doubt, a condition of atrophy of the ovaries in such cases, and their removal produced the effect which he should have expected.

On Fœtal Extensions or Retroflexions during Pregnancy, by Drs. MATTHEWS DUNCAN and HURRY.—The authors have collected all examples of extension of the limbs or body of the fœtus occurring during pregnancy, and have tried to throw light on their causation. These extensions may be of a leg, or of both legs, or of the whole body. They may be caused by malformation, goitre, amniotic bands, exomphalos, shortness of cord, and morbid conditions of the mother.—The PRESIDENT remarked on the special value of the paper as throwing light on some of the causes of face presentations.—Dr. CHAMPNEYS said that the only variety he had himself observed was the "siége décomplété" (Lefour). In this, when primary, the legs after birth at once resume the fœtal attitude and fly up over the shoulders in a most striking manner.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

AT the ordinary meeting of this Society, held on June 7th, Dr. Thudichum, President, in the chair,

Dr. H. CAMPBELL POPE read a case of Littré's Operation of Inguinal Colotomy for Congenital Deficiency of Rectum. The child when first seen, two days after birth, was vomiting a greenish-coloured watery fluid; it was dusky in appearance. The abdomen was immensely [illegible]nded with flatus, especially in the course of the c[illegible]mina-tion per anum the finger entered a cul-de-sac about one inch in depth, and of the o dinary calibre of an infant's bowel. No upper sac or protrusion could be felt, but when the child strained a general bulging could be distinguished. Fifty hours after birth a trocar was passed from the extremity of the cul-de-sac into the pelvis in the usual direction of the rectum. This proceeding was followed by the escape of about two drachms of straw-coloured odourless fluid, and on introducing the trocar still further a little meconium escaped. As the fluid was apparently from the peritoneal cavity, it was decided to open the sigmoid flexure of the colon after Littré's method. An incision about an inch and a half in length was made above and parallel to Poupart's ligament, and on opening the peritoneal cavity six drachms of straw-coloured fluid escaped. The large bowel was seen to end in a free floating extremity. It was opened by an incision in its long axis and fastened to the external opening by four sutures. No further vomiting occurred after the operation. The child did well for the first fortnight and the wound healed; but after this time the gut began to evert, and a large portion, three inches long, became constricted and ultimately sloughed off. This process again recurred and a further portion, two inches in length, sloughed off. After this the progress was entirely satisfactory, and twelve months after birth a perfect artificial anus, capable of retaining fæces, resulted. Ultimately, the child died of hæmorrhagic measles when thirteen months old. Dr. Pope recommended in cases where the bowel could not be satisfactorily reached from the anal cul-de-sac that an exploratory abdominal incision should be made (as for inguinal colotomy) and the end of the bowel examined. If feasible, it should be brought down to the anal cul-de-sac and fastened to it, an incision having been made in the upper extremity of the cul-de-sac. If this could not be done, Littré's operation might be concluded.—Dr. TRAVERS did not advocate the use of the trocar but careful dissection from the anus, keeping close to the sacrum. Where the gut could not be reached thus, he would perform Littré's operation.—Dr. THUDICHUM agreed with the suggestion as to an exploratory abdominal incision.—Dr. ALDERSON had a case in which, after a prolonged operation from the anus, the child died from collapse two hours after.—Dr. POPE, in reply, agreed with avoiding the use of the trocar, and condemned very prolonged operations from the anus.

Surgeon-Major T. H. HENDLEY read a paper on the Van Ryselberghe Meteorograph, which had been installed under his superintendence in the meteorological observatory of H. H. the Maharajah of Jeepore, in India. In reply to Dr. Thudichum, Surgeon-Major Hendley said that there was a special department in India under Mr. Blandford, F.R.S., meteorological reporter to the Government of India. The relation of meteorology to medicine was not lost sight of, but it would of course require time and labour to obtain valuable results.

Dr. KILNER read a paper on Peripheral Lesions as the Exciting Cause of Chorea. Seven cases were quoted in support of the theory. The lesions in these cases being due to rheumatism, dentition, ovarian and uterine disease, masturbation in the male, and various causes in one case. Afterwards it was stated that it was extremely probable that in nearly every instance an exciting peripheral lesion could be found as well as a central derangement. For shortness' sake, the central derangement, whatever it may be, was called hyperkinesis, and the peripheral lesion the excitor. It was considered that if the hyperkinesis was not very great the excitor must necessarily be powerful; on the other hand, if the hyperkinesis be intense the excitor need only be mild; and when both the hyperkinesis and the excitor were intense a severe attack of chorea may be expected. It is also extremely unlikely that the hyperkinesis of itself produces chorea, because before it becomes sufficiently great to cause an attack an excitor will arise, as the system can hardly be considered in a perfect state of health, but this excitor may be so slight as to be easily overlooked. In one of the cases quoted the natural functions of menstruation was sufficient to determine an attack.—Dr. THUDICHUM said the commonest cause of irritability was some chemical change in the nervous system.

Mr. H. H. TAYLOR showed Two Kidneys affected with Cystic Disease. They each weighed about four pounds. They consisted of congeries of cysts, varying from the size of a marble to an orange. None of the cysts were within other cysts. They contained, some a clear fluid, others milky, some dark but clear, others dark and thick. No renal tissue could be found.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting of the Medico-Psychological Association was held on Wednesday, July 23rd, at the Royal College of Physicians, London; Dr. Rayner, the President, in the chair. Among other business, Dr. J. A. Eames was elected to be President for the ensuing year, and it was agreed that the next annual meeting should be held in Ireland.

The PRESIDENT, in his opening address, dwelt on the delays to treatment by the present system of certification of the insane, and asserted that loss of chance of recovery, suicide, and other lamentable occurrences, resulted directly or indirectly from it. He deprecated any increase of the obstructions to placing an insane person under treatment, and advocated that every patient should be examined by a State medical official as soon as possible afterwards. He took the view that to abolish private asylums would logically involve the abolition of the care of single patients, which was regarded by many authorities as the most satisfactory mode of treatment. He recommended the addition of at least four medical commissioners to the present Lunacy Board, and an increase of the pay of the Commissioners in Lunacy. After alluding to various causes which might tend to reduce the development of insanity, and giving a summary of the progress in treatment, he suggested that any additional accommodation for the insane hereafter provided should be specially adapted to recent insanity. In conclusion, he expressed the expectation that at no distant date an arrest would occur in the present rate of development of insanity.

It was announced that the adjudicators had awarded the Association medal and money prize (which is open to competition to assistant medical officers of asylums) to Dr. Macphail of Garlands Asylum, Carlisle, an asylum from which good work has already emanated. This essay is entitled "Clinical Observations on the Blood of the Insane." We shall hope to touch further on it when it is published, which no doubt it will be shortly, as it becomes the property of the Association. The adjudicators were Prof. Gairdner and Drs. Orange and Rayner, the present president and his two immediate predecessors.

The members of the Association afterwards dined together at the "Ship" at Greenwich.

Reviews and Notices of Books.

The Guide to the Study of Ear Disease. By P. M'BRIDE, M.D. Edinburgh: W. and A. K. Johnstone.
Manual of Diseases of the Ear. By THOMAS BARR, M.D. &c. Glasgow: Maclehose and Sons.

THE first of these works, the author states, is intended to meet the requirements of the student and of the general practitioner who have not the advantage of studying otology under the guidance of a teacher. If it were said that an account is given of the various methods of treatment which are to be found in the text-books, to which reference is freely given—and the reader is left in some doubt how to choose between them,—it would, we think, more accurately describe the impression which is left after a perusal of this little book. To give one example. When speaking of the large subject of perforations of the tympanum, all the numerous applications which are in use and have been employed are mentioned, but the local conditions, appearances, symptoms, &c., for which each application is especially suited, are left to the student to discover for himself; and when it is said of the "artificial tympanum" that that of the late Mr. Toynbee is the one "most commonly used," a scarcely correct idea is conveyed of what is the practice with the chief aurists in this country or abroad. The record of symptoms which should make necessary an opening of the mastoid cells is most meagre, and the directions given are simply that a chisel or small trephine may be used, and the instrument directed forwards rather than backwards. The illustrations, however, are very well executed, and a very fair summary is given of the different operations on the membrana which have from time to time been suggested and practised.

The ordinary diseases of the ear are well described in Dr. Barr's manual, and whilst each disorder is under discussion, very full references are made to the writings of Continental aurists. The account which is given of the methods of examination is especially clear, as is also that portion of the book which deals with operations on the membrana tympani, a subject that is fairly discussed, and one on which it is most desirable that the general opinion entertained by those competent to judge should be freely diffused. As a manual the book is unusually large, containing nearly five hundred pages, but this may be excused in consideration of the fact that so few details of the subject have been omitted.

An Elementary Course of Botany. By the late Professor HENFREY, F.R.S. Fourth Edition, by M. T. MASTERS, M.D., F.R.S., and A. W. BENNETT, M.A., B.Sc. Pp. 724. London: Van Voorst. 1884.
The Student's Guide to Systematic Botany. By ROBERT BENTLEY, F.L.S. Pp. 178. London: J. and A. Churchill. 1884.
Aids to Botany. By ARMAND SEMPLE. Second Edition. Pp. 103. London: Baillière, Tindall, and Cox. 1883.

THE fourth edition of Henfrey's well-known and justly esteemed work, while not occupying more space than heretofore, contains a large amount of new matter, especially in the morphological, histological, and physiological sections. It has evidently undergone careful revision at the hands of the editors, some passages of less importance having been omitted to make room for newer or more useful information. In the systematic portion of the work the natural orders have been arranged in accordance with Bentham and Hooker's "Genera Plantarum," although the editors have not hesitated to point out cases in which they differ in opinion from those veteran botanists. It must be a matter of no small difficulty to condense, as is done in the present work, the immense amount of botanical information yearly issuing from the press in such a manner as to render it available for the use of students, and to duly weigh results which appear contradictory, while endeavouring at the same time to keep up to date with the progress of botanical science. For the benefit of those who are unacquainted with Henfrey's "Elementary Course of Botany," it may be stated that the plan of the book is to lead the student by easy stages from a consideration of the various organs of plants, and the method of describing them, to a knowledge of their classification, the more difficult details of microscopical structure and of the physiology of plant life being subsequently described; while geographical and geological botany are reserved to the last. The subject matter is rendered easily comprehensible by typographical devices, certain necessary digressions, and additional or explanatory notes being printed in smaller type, and the more important matter and the larger natural orders of plants being indicated by large type. The explanatory notes on the affinities of the natural orders form an important feature in this work, and tend to give a much clearer idea of the classification of plants than could be obtained from a bare description of the botanical characters of each order. The prominence given to facts rather than to botanical terms is another advantage which the student will not be slow to appreciate. Exception might perhaps be taken to one or two points in the cryptogamic section, such as the retention of Phascaceæ (p. 404) as a distinct group of mosses, these plants being now more correctly distributed by bryologists amongst the various families of Bryaceæ, to which their structure indicates that they rightly belong, and of which there can be little doubt that they are degenerate or undeveloped forms. The Ricciaceæ (p. 407) have no more claim to be considered as exclusively aquatic plants than the Ranunculaceæ. Nor can we agree with Mr. Bennett in the statement that the compound nature of lichens has been completely established,

Digitized by Google

seeing that the Schwendenerian theory is not yet accepted by the majority of lichenologists. But, these are minor matters of comparatively little importance to the student of medicine, and in no way detract from the usefulness of a book which may be considered one of the best of the manuals of botany that can be placed in the hands of a student of any branch of the science, and of which every botanist ought to have a copy in his library.

Those who have been accustomed to carry to and fro from botanical gardens Bentley's well-known "Manual of Botany," by the same author, will feel grateful to him for providing this portable little guide. It is of a convenient size for the pocket, and contains the whole of the descriptions of the natural orders of plants, as given in his larger work. This condensation has been effected by omitting all details relating to the economic uses of the plants of each order. A very useful feature in the book is a chapter on descriptive botany, with illustrative descriptions of several medicinal plants. As a pocket companion, to be used when studying practical botany, the book will be invaluable both to the student and to the more advanced botanist. The only subject of regret is that the author has not followed the mode of classification adopted in Bentham and Hooker's "Genera Plantarum," which will undoubtedly be the standard work used by British systematic botanists both at home and abroad for many years to come. In a future edition, which we hope may soon be called for, this point might be easily remedied. The addition of a few notes conveying some idea of the alliances of the different natural orders to each other would not add much to the bulk of the work, and would be very useful to more advanced students.

The second edition of Mr. Semple's little work, according to the statement in the preface, has been almost entirely rewritten and a considerable amount of new matter added. Its object is to place before the student the leading points of the science in the plainest language possible. At the present day, owing to the rapid strides made in all branches of medical science, there is a tendency to consider botany as one of the least important of the sciences with which the medical student must be acquainted, and hence probably the attempt to make it as simple as possible. The plainness of the language adopted throughout the book is in some cases at the expense of accuracy. Looked at from a purely botanical point of view, it cannot be used with advantage as an introduction to a more extensive study of botany, for the student would have to unlearn many of the statements contained in it, and unless its perusal is accompanied by a practical study of plants in the living state, it can only serve as a means of "cramming" the subject. It used to remind the student of the meaning of the principal botanical terms before going up for an examination, care should be taken to correct, by a reference to the Pharmacopœia, such statements as the following—viz., that arnica, jalap, and serpentary are roots (p. 7), that the leaves of Uncaria Gambir, the flowers of ammoniacum (p. 23), and the fruit of rue (p. 35), are the officinal parts, or that ergot is a seed (p. 67). The index is an excellent one, and the chief advantages that the brochure appears to possess over works of a similar character are that it gives a list of the parts of the plants officinal in the British Pharmacopœia under the different organs of plants, and that it contains a synopsis of the characters of the principal natural orders affording medicinal plants.

ON the 23rd inst., certificates of efficiency were presented to those members of the Edinburgh Ambulance Corps who had passed the examinations. The number of certificates presented was 285. At the close of the proceedings, a number of persons enrolled themselves to form the nucleus of a Volunteer Artisan Ambulance Corps.

THE RIGHT USE OF REFUSE.

THIS was the title of a lecture given by Dr. Poore at the Health Exhibition on Tuesday last, Professor Tyndall occupying the chair. There was a large and most attentive audience. Dr. Poore remarked that nowadays sewer air or sewer gas was one of the staples of conversation in all society, and the elders of the present generation often wondered why it was that in their young days this subject was comparatively unknown. The reason was not far to seek, and lay in the fact that the present generation had been engaged for some years in the wholesale manufacture of sewer gas, which was a product of sewers and water-carried sewage, whereas our parents dealt with their refuse in a less wholesale fashion, and had not, as we have, sewers laid on to the very interior of their houses. The particulate and organic nature of the poison of some of the zymotic diseases had been definitely proved, and with regard to others it was a matter of the very highest probability. After giving the life history of the bacillus anthracis, and showing how it might be propagated artificially, and what were the conditions (moisture, warmth, darkness) which were favourable to its growth, the lecturer said we could hardly escape from the conviction that bacilli and allied organisms might grow in sewage, and especially in warm, dark sewers or cesspools. Apart from this fact, the knowledge that these poisons were particulate, and that each particle was alive and capable of infinite increase, made it very undesirable to disseminate these poisons in a great volume of water and allow them to trickle, nobody knew where, until an outburst of epidemic disease disclosed the unforeseen track which the poison had taken. Bacilli, it was well known, were killed by dryness, and in times of panic, like the present, dry methods of treating excreta were recommended. If dry methods were good in times of panic they must be good always, and it was well known that no spread of disease had been traced to the dry earth method or to the other dry methods (like that in use at Manchester) of treating excreta. Great sewerage schemes were seldom an unmixed good. They encouraged overcrowding by enabling houses to be built without any curtilage whatever, and without any outlet for filth except by the sewer. The density of population in London had increased in many parts, and with the result that those diseases which were propagated by aerial infection, such as measles and whooping-cough, to say the least, had not decreased. If a great sewerage scheme were carried out in the Valley of the Thames, that district would soon be overcrowded, and the amount of sewage to be dealt with would steadily increase. It must be borne in mind that although it was comparatively easy to lay pipes, the question of how to treat a great mass of sewage when it had been collected had not yet been settled. Nobody contended that chemical methods would render sewage wholesome, although they might clarify it to some extent. If a great outfall were established at Mortlake, it certainly would not be advisable to drink the water or to bathe in its neighbourhood. The great difficulty and expense being the treatment of sewage when collected, it was clearly to the interest of sanitary authorities to encourage the inhabitants to send as little sewage to the outfall as possible. In a district of villas and market gardens there should be no difficulty in treating sewage, and it could be done more efficiently and economically close to the house than elsewhere. The villa holder should be encouraged to deal with his own refuse on his own premises, and the way to encourage him was to have an equitable adjustment of sanitary rates so that the householder who dealt efficiently with his own refuse should pay less than he who left his refuse and filth to be dealt with by the public authority. The reverse was too often the case. A house to be securely healthy should have no collections of putrescible matter near it, and to avoid this it was necessary to use earth closets and apply the slops directly to the soil.—Professor Tyndall, in moving a vote of thanks, expressed his general concurrence with the lecturer, and dwelt upon the importance, under existing circumstances, of thoroughly disinfecting the excreta of cholera patients before allowing them to pass into the sewer.

THE LANCET.

LONDON: SATURDAY, JULY 26, 1884.

THERE is yet time for all parties to save their credit in the matter of the Medical Bill. If this short period is misused very serious discredit will accrue. Many of the existing authorities may be beginning now to congratulate themselves on the prospect of another lease of present privileges. It is very easy to defeat legislation. Parliament, with its interminable talk, its party exigencies, and its iron rules, is a very poor business instrument. But to defeat legislation is not to re-establish credit. The great universities of Scotland may yet show themselves not afraid of an independent test of the work they do. The great corporations of England and Ireland may yet take their proper place in a system which will abolish the half diplomas in which they chiefly deal, leaving to the joint corporations of Scotland an easy and lucrative trade in double qualifications. It is lamentable to think that, by the failure of the present attempts at legislation, the great Colleges of Surgeons of England and of Ireland—to say nothing of the Colleges of Physicians—may be doomed to years of legal incompetence to grant other than half diplomas. But this is the meaning of the miscarriage of the Government Bill. The authors of the series of amendments may yet escape the charge of wholesale and deliberate obstruction. The medical members of Parliament may yet show some sympathy with their brethren of the profession and share the honour of legislation demanded by medical men and required for the public advantage.

There remain two parties to the success of the Bill or to its failure, to the gratification of the profession or to its disappointment. One of these is the Government itself. No Government has ever shown more earnestness or taken more trouble to promote legislation on a sound basis than this one. Mr. GLADSTONE himself, in one or two sentences, has indicated his large conception of what is needed to make the profession one—to make it self-respecting and respected by the public. Lord CARLINGFORD and Mr. MUNDELLA have respectively taken unprecedented pains to place the subject fairly before Parliament and to get the best result possible. It will be regrettable if at the last moment the Government lacks faith either in its own Bill or in its power to pass it. It is not the fault of the medical schools or the medical profession that it has been postponed to the end of July; neither, perhaps, is it altogether the fault of the Government that night after night, instead of appearing in its promised place on the order list, it appears last, or is compelled by its absence. We implored the Government to pass the Bill and to adhere to the original principle of it, as embodied in the Report of the Commissioners, including an independent Final Board. There are always troublesome outsiders of their own party who exact from a Government unreasonable terms in exchange for their support. On this occasion Sir LEON PLAYFAIR is doing so. In a speech the fullness of which we have cited to-day, he has done more harm to the Bill by faint praise than good by his approval. He has proposed an amendment which in our opinion is not an improvement. He proposes to require the Council to accept, in lieu of a final and conjoint examination arranged by the divisional boards, the admission of assessors in the various examinations of the existing licensing authorities. He must know that this change is not acceptable to the body of the profession, though doubtless he hopes by it to conciliate his supporters in Scotland. It is the weakness of Sir LEON PLAYFAIR'S position at this juncture that he is between two fires—very hot ones too—those of the corporations on the one hand and those of the universities on the other. He does not seem to see that the way to make the universities of Scotland greater still is to regard them as imperial institutions doing imperial work, and bound therefore not to shirk imperial tests. We trust that he will not be too exacting on the Government, and that he will not paralyse the future Medical Council. There is only one condition upon which we can agree to his amendment, and that is, that he shall give the Council discretionary power in any given case to dispense with a Final Board. To compel it to do so is to tie its hands and to make it impotent for good.

LAST week the grievances of the Indian Medical Service were brought under the consideration of the House of Commons by Mr. GIBSON, in a very temperate speech, concluding with a motion, "That the condition of the East Indian Medical Service calls for the early attention of Her Majesty's Government, and this House trusts that steps will soon be taken to lessen the block in promotion and the disappointment at the methods of employment and pay which exist in its ranks." After a well-merited compliment to the service, which "has in its ranks now, and has had in the past, many distinguished men, and has always in times of cholera and danger been loyal to its duties," Mr. GIBSON proceeded to point out the grievances complained of by its members under two heads—those of the *senior* medical officers, and the grievances and disappointments of the juniors. Under the former, he adduced the reduction of the number of administrative appointments and the abolition of the privileges guaranteed to the service at the time they entered it, under the Government of India Act. While the strength of the medical service had been reduced by 20 per cent., the number of administrative appointments had been diminished by 33 per cent. The system of promotion by seniority had been modified, and that of selection for the administrative appointments introduced, without any compensation being awarded to the officers who were thus passed over; and a rule had been introduced by which officers who declined promotion when offered would be permanently passed over. These appeared to be the grievances of the senior officers. Those of the junior were of a different nature. They complained that by the terms of the Government circular, under the conditions of which they had entered the service, they understood that as soon as they passed the examination in Hindustani they would become entitled to a higher rate of pay, however employed; while the Government held that they were entitled to this increase only when employed in certain appointments. They also complained that the rate of pay—absurdly called *unemployed* pay,—which was to be temporary and exceptional, had of late been so much the rule that in many instances officers

Digitized by Google

did not get the increase to which they conceived they were entitled until they had served five or even six years in India. The motion was seconded by Sir LYON PLAYFAIR, who adduced several instances known to himself in which the system in operation had inflicted great hardship. But we were surprised to see that he talked about the young officers just arrived from Netley being put under the charge of their seniors, "whose special qualifications were not equal to those of the students placed under them," as being the practice "of placing the superior under the command of the inferior"; and quoted Professor MACLEAN of Netley as the author of this sage remark.

Mr. CROSS, with great justice, congratulated the Indian medical officers on the ability and moderation with which their case had been stated; but he contended that it was impossible, in the interests of the public, to argue that there should be no reduction in the number of administrative appointments if the Government should consider it advisable. With regard to the complaints of the junior medical officers, he pointed out that the slowness of promotion was an unavoidable result of the necessity for increasing the numbers of medical officers during the Afghan war, but that this stagnation was apparently now approaching an end, and he quoted figures to show that the number on unemployed pay was rapidly diminishing. With regard to the charge that the Government had not kept faith in the matter of increase of pay after the Hindustani examination had been passed, he maintained that the conditions had been faithfully observed, and that the charge was founded on an erroneous interpretation of the obvious meaning of the paragraph, which was restrictive, and not declaratory, of the persons entitled to draw the increase. He also pointed out that the regulations as to *officiating* pay, of which complaint had been made, were applicable to all branches of the Indian Service, and were necessary to enable the Government to keep up such a reserve of officers as would permit them to grant furloughs without involving a large addition to the expenses of the different departments. Mr. CROSS then showed that although in some respects the Indian medical officers were not so well situated as those of the Army Medical Department at the commencement of their career, their prospects were much better after a few years' service, and also as regarded their pensions. After a discussion, in which several members took part, the motion was negatived without a division.

From a careful study of the whole subject, we see no reason to alter the conclusions at which we arrived when the Indian Medical Warrant was issued: that the changes involved in it were necessary in view of the altered condition of the army, and that, as far as regards the senior officers, the arrangements ought to be deemed satisfactory. With regard to the grievances of the junior officers, we are still of opinion that a revision of the system of so-called unemployed pay is urgently needed, that it may, to use Mr. GIBSON'S words, "be put on something like a rational basis." Dr. FARQUHARSON observed that, "as to unemployed pay, he did not see why such an unmeaning term should not be abolished, and why some general arrangement should not be come to by which pay might be given for admitted employment on different scales." The modifications consequent upon the changes introduced into the hospital system seem imperatively to require a reconsideration of the whole system of charge pay and allowances. On another point a change seems called for—that of compelling officers to "pay their way to all appointments in which they draw higher pay." We believe that in many instances, especially of officiating appointments, this rule inflicts a grievous injustice upon the officer, who may not be able, from circumstances not under his control, to hold the appointment long enough to recoup him the expense to which he is thus put. Except in cases where the change is made at the officer's own request and for his convenience, the expense of the removal should be borne by the Government. Mr. CROSS has promised to bring Mr. GIBSON'S statement of the grievances of the medical officers to the notice of the Government of India, and we trust he will back it up with a strong recommendation in favour of the amelioration of the service in these important points.

THE statement made in the House of Commons last week by Sir CHARLES DILKE shows that the action of the Select Committee in throwing out the Lower Thames Valley Main Drainage Scheme, which had been unanimously approved by the Main Sewerage Board, and confirmed, after a careful inquiry, by the Local Government Board, was a gross and unwarrantable blunder, likely to be followed by the most disastrous consequences. If the scheme had been approved by the Committee, Parliamentary powers would have been conferred upon the Main Sewerage Board which would have enabled them to carry the sewage of the whole area to a single spot near Mortlake, purify it by precipitation, and also, we believe, by land filtration, throw into the river a tolerably clear and practically harmless effluent, instead of the raw sewage which now defiles it. We do not pretend that the scheme is perfect. Whatever precipitating process is used, the effluent water is never pure, and the solid portion is always to some extent offensive. The process selected by the Board was that of the Rivers Purification Association now in use at Coventry and elsewhere. The sewage is mixed with lime and the sulphates of iron and alumina, which precipitate the solids, and, if the subsidence reservoirs are large enough, gives a clear and by no means objectionable effluent. The solids are partially dried by a filter press, and form a manure which has a certain value, though not a great one. The Main Sewerage Board proposed to carry this sewage-cake in barges to a spot near Rainham in Essex, where, according to scientific evidence, it would cause no nuisance. The defects of the system are obvious, and it may furthermore be conceded that it would be difficult, if not impossible, to turn out a satisfactory effluent in times of flood; that we take to be the greatest objection to the system as at present worked.

But the reply to all such objections are the obvious questions—What else can be done? What better scheme is offered? The sewage of more than a hundred thousand persons is to be disposed of, and it is admitted by nearly everyone that it must, under existing conditions, go into the river. The system indicated in the attractive motto, "The sewage to the soil, the rainfall to the river," is for the present impracticable, and the task of practical administrators is limited to the purification of the sewage as much

Digitized by Google

as possible before it joins the rainfall in the inevitable river. Experience has shown that the system now under consideration is capable of effecting a fair purification of sewage without perceptible nuisance, and at moderate cost. We do not say that it is the best of all possible systems, but we hold that the immediate adoption of some system is absolutely necessary, and that no other is at present proposed. As for the objections of individuals, it is impossible to imagine any method of treatment which would not inflict injury, real or imaginary, on someone. If anyone is injured, he must be compensated—that is all.

The conduct of the Committee in regard to this carefully prepared scheme has been so extraordinary that we will not attempt to account for it. Not only have they rejected the scheme, but they have recommended the rejection of an unopposed order which would have protected the Main Sewerage Board and the ratepayers from the liability which under the Thames Conservancy Act they will now incur after September next. They rejected the scheme almost contemptuously. They heard the evidence of only two out of the eleven constituent authorities, they did not even listen to the Main Sewerage Board appointed to find a remedy for the evils so long complained of, and, as far as we can understand, found no fault with the suggested system. The essence of their report is the general suggestion which we noticed last week, that the district should be divided into four or five smaller districts, each of which should undertake the purification of its own sewage, and this suggestion appears to us a most unwise one.

In favour of the proposal one argument may fairly be urged. To ensure the most rapid oxidation it would, no doubt, be better that the sewage effluent should enter the river at several places instead of at one, and it is open to question whether, if the scheme of the Board had been carried, it might not have been found possible to discharge the effluent at several points not too near together. But the rejection of the whole scheme on this ground will, it appears to us, lead to a waste of time and money utterly out of proportion to the defect alleged as excuse. The long-continued pollution of the river in the Richmond and Kew districts has been caused mainly by the opposition which each sanitary authority has met with in its attempts to gain sanction for its pet scheme. If four or five small boards are now turned loose to deal independently with their sewage difficulties, they will meet at once with the old opposition, strengthened and encouraged by previous victory. In the most favourable case the purification of the river could not be attempted before 1886, and there is but too much reason to fear that it will be indefinitely delayed. That would be a terrible risk. An imperfect remedy is better than none, and it is, above all, necessary that some remedy shall be applied without further delay.

As for the condition of the Thames below London, all that can be said is that it is about as bad as it can be. It is literally dangerous to breathe its air; and we have heard of cases of sickness and diarrhœa obviously traceable to its noxious exhalations. The Metropolitan Board of Works, who have expended large sums of money in demonstrating its purity, seem at last to have awakened from their delusion, and are making efforts as futile as frantic to disinfect the sewage. We can hardly believe it to be true, but a report reaches us that they actually contemplate the manufacture of chemicals for the disinfection of the sewage of all London. The public who pay for it ought to know how much the so-called disinfection is costing per diem.

Two matters of especial interest in connexion with the question of Lunacy Law Reform are always before the public, and we cannot doubt that it is mainly because of this very persistence of their appeal, whether mute or clamorous, for prompt consideration, the claim is disregarded. Consciously or unconsciously, public opinion grows obdurate to the demands of a continuous need; and "burning questions," unless they can be artificially, or are fortuitously, blown into a flame every now and again, are, for the most part, left to burn themselves out. It is so with this question of Lunacy Law Reform. The two matters of especial interest to which we allude are the farcical character of the Commissioners' inspection and control of asylums and the system of private or "licensed" houses. We scarcely know which of these scandals—for such they unquestionably are—should be regarded as the more discreditable.

It reflects seriously on the common-sense of the country that £15,159 per annum should be wasted in the maintenance of a Commission which, whatever it has been in the past, has now ceased to be anything except an effete body, giving only, now and again, a peevish kick at some unoffending individual in order to show that it is still so far alive as to be able to draw the public moneys allotted to it. As regards even the inspection of houses for the residence of the insane, the Commission is of no possible use to the community. If any proof were needed of this fact, it would be supplied by the last fearful calamity of asylum-burning, when a house notoriously unsafe was licensed and periodically inspected—save the mark!—by the oligarchy of "extinct volcanoes" at Whitehall. While as to the protection of the insane, the sort of efficiency with which the Commission does its work may be judged from the fact that whenever any question arises, the noble chairman—whom everybody personally respects—is put up to say that the "certificates" given are carefully examined and found correct, and that no grave breaches of the Lunacy Law are known to the Commissioners; whereas everybody is well aware that the correctness of the certificates simply relates to the technical filling in of the forms, without the most distant reference to their truthfulness.

As regards breaches of the Lunacy Law, the Commissioners seem to become aware of what is being done, if we may judge from the inquiries they make from time to time, about two years after its occurrence! Probably few things in public business are so "ripe" as the agenda of the Commission in Lunacy, except it be the information received or acquired by the Lord Chancellor as to what is going on in the lunacy department under his jurisdiction. It will be within the recollection of our readers how the noble lord on the Woolsack, when the Earl of MILLTOWN raised a very useful discussion in the House of Lords some time since, had to send to the library for books to give him a few facts for his speech in defence of the *status quo*, and how it was evident from what the Lord Chancellor cited and said on the subject that he knew nothing whatever about what had been going on during the last few years, and was barely

Digitized by Google

aware that the question of reform had been mooted Indeed nothing so comic has occurred in connexion with any debate in either House of Parliament on a grave question within our memory as the noble lord's *naïf* betrayal of ignorance of the subject. His production of fossil figures and facts with much solemnity calls to mind the story of the unhappy parson in a civic pulpit, who, having forgotten his sermon, was fain to read one chained to the desk, which happened to have been written in the time of the Great Plague. Lord SELBORNE'S information on the subject was many years old.

The private asylum system, and all it implies and involves, is again thrust upon public attention by criticisms in the House of Commons and by proceedings before courts of law. It is not on individual cases and complainings this question should be made to rest. A most grievous facility for wrong-doing undoubtedly exists It is not necessary to prove that wrong has actually been done. We would be willing to admit, for the sake of argument, that no single case against a private asylum proprietor has ever been clearly made out; nevertheless, we must contend that a system so utterly unsafe, and obviously inexpedient and indefensible as that which makes the retention of lunatics in asylums a matter of trade policy, ought not for a single instant to be tolerated. We have compared the private asylum system to that of the old "sponging houses," and the comparison has been resented. It is, however, accurately apposite and complete. Both as regards the mode of incarceration and the power and manner of detention the two sets of houses are on all fours. We are prepared to demonstrate the analogy at all points if anyone cares or dares again to challenge it. We repeat, and shall continue to reiterate until reform is conceded, that the laws which govern the custody — we will not say the medical treatment—of the insane are a scandal to the country.

THE doctrine of the infectivity of tubercle is mainly based upon the results of experimental inoculation, and the belief in the transference of the tubercular virus by inhalation is grounded on similar experience. It was to test the value of such observations that Dr. WARGUNIN has been conducting experiments in Prof. RAJEWSKY'S laboratory at St. Petersburg, which are recorded in the current number of VIRCHOW'S *Archiv*. The experiments were made upon dogs, and consisted of three series. In the first series the animal was caused to inhale an atmosphere charged with products of phthisical sputum, in the second with similar material after disinfection by carbolic acid and by heat, and in the third with indifferent substances, as particles of flour, cheese, and the dried products of bronchitic sputum. In all the dogs submitted to the first process the lungs became the seat of changes having the macroscopical characters of miliary tubercle, and this whether the "dust" was inhaled in the dry state or with vapour. It appeared, however, that when an animal was placed under better hygienic conditions, it could recover from the effects so produced—effects all the more striking, since tubercular affections are rare among the canine species. These results are in harmony with those previously obtained by TAPPEINER and others, and at first sight would seem to confirm the doctrine of the infectivity of tubercle. But it was found that the same effects were produced in one out of three cases by the inhalation of previously disinfected sputum; and the question arose whether, after all, such effects could be attributed to specific infection rather than to merely mechanical irritation of the lung by the finely divided particles. At the same time, admitting the infective view, it was conceivable that the disinfecting process had not been thorough enough, and that the virus still remained operative. It was with a view of testing this point that the third series of experiments was undertaken. Here the material employed was destitute of any specific qualities, and yet the lungs became the seat of changes indistinguishable from those set up by the inhalation of phthisical products.

It now became necessary to ascertain whether the nodules which bore a general similarity to tubercle were really of that nature, or whether they essentially consisted in inflammatory material excited by the presence of foreign bodies. It is unfortunate that this research was mainly completed before KOCH'S discovery of a bacillus was known to the observer, so that the detection of this micro-organism as a test of the tubercular nature of a morbid process could not be utilised. This fact deprives WARGUNIN'S research of some of its importance, and must necessitate a repetition of these experiments. Apart, however, from the presence or absence of the bacillus, histological examination pointed to a simple inflammatory rather than a tubercular change; for the process appeared to commence as a cell growth within the smaller bronchioles, leading to their occlusion. In some parts this change was limited to the mucosa, in others it spread to the adventitia. The cells which blocked the lumen of the bronchiole were spindle-shaped, the deeper ones lying nearest the wall being spherical; but as the new tissue contained no bloodvessels, it speedily underwent fatty degeneration. It would appear, then, to be something more than a mere catarrhal process, since the cells showed a tendency to become organised; the lack of vascular supply, however, arresting the process. In the alveoli there was a large production of young cells, apparently from the epithelium, and the nodules thus formed underwent fatty degeneration. Similar nodules, but undergoing casation more rapidly, and presenting fewer features of granulation tissue, were produced in the rabbits long after the inhalation of the products of phthisical sputum. It would seem as if in the rabbit the irritant produced changes more rapidly than in the dog. Anatomically, then, the lesions did not conform to the typical structure of tubercle; and the limitation of the process to the lungs, the absence of general symptoms, and the fact that those animals which, after the inhalation were placed in good hygienic conditions, recovered, pointed to the conclusion that the induced disease was not tuberculosis, but a local inflammatory process—a broncho-pneumonia excited by the contact of foreign solid particles.

It is interesting to turn from the perusal of these researches to the statements by KOCH in his elaborate report on the Etiology of Tuberculosis ("Mitth. aus d. Kais. Gesundh.," Bd. ii.) KOCH employed for his inhalation experiments the cultures of bacilli obtained from phthisical cavities, and submitted rabbits, guinea-pigs, rats, and mice to an atmosphere charged with these products suspended in water, the inhalation being conducted for the space of half an hour on three successive days; the animals being then placed in separate

Digitized by Google

and spacious cages. Three rabbits and four guinea-pigs died within fourteen to twenty-five days, and the remainder were killed twenty-eight days after the last inhalation. In all of the rabbits and guinea-pigs the lungs contained numerous tubercles, which were also present in the liver and spleen of those that survived longest. These tubercles when of large size extended into the alveoli of a whole lobule, and thus formed nodules of considerable size, studded with yellowish points corresponding to the caseated alveolar contents. In fact the larger masses reproduced the characters of caseous broncho-pneumonia, just as in the spontaneous tuberculosis of these rodents. The only differences from the above in the case of rats and mice lay in the less abundance and smaller size of the tubercular nodules. In all the instances the tubercles presented the typical character of the growth in the presence and disposition of epithelioid giant cells and of bacilli. Moreover, KOCH transmitted the disease from these animals by inoculation.

From these explicit statements of KOCH we turn to WARGUNIN'S paper in the hope that some means of reconciling the different results may there be found. Instead of this we only meet with the assertion that the etiology of tubercle is not so simple as KOCH asserts. For if it be so, says WARGUNIN, and if all that is necessary to develop pulmonary tubercle is exposure of the lung to the virus, especially if the protective epithelium be injured, then every bronchitic subject should be in danger of becoming phthisical. Moreover, he is not satisfied with any of the numerous inhalation experiments hitherto conducted, averring that more attention has been paid to the general macroscopical features of the lesion than to its histological characters; and that account has not been taken of the occurrence of antecedent pathological processes, or of the famous dictum of BUHL as to caseation inducing tuberculosis. SCHOTTELIUS appears to be the only observer who has regarded the effects of the inhalation experiments in the light here expressed by WARGUNIN,—with this difference, that SCHOTTELIUS considers the first effect to be upon the alveoli, the bronchial change being secondary.

We have thought it well to direct attention to this paper, which is unfortunately defective in several points (and chiefly in the scanty attention paid to KOCH'S experiments), because the main significance of the subject rests in the solution of the question raised within it. That tubercle is transmissible by inhalation is the foremost question of all, for it lies at the root of the alleged contagiousness of phthisis. It is in this direction that the medical world must look for definite and conclusive statements from experimental pathologists, based on thorough investigations undertaken without bias or prejudice.

MANY points of great public interest were raised in the recent Conference on Adulteration at the Health Exhibition. Dr. BUEL, whose address, presented in abstract in our last number, opened the proceedings, spoke, in language the strength for its impartiality and moderation, of some of the defects of the present Acts. Dr. ODLING, who, as President of the Institute of Chemistry, presided, confined himself to a summary of the subjects requiring consideration; but many of these subjects were discussed by subsequent speakers, many of whom, though not all, were well-known public analysts. The speeches by Dr. DUPRÉ, Mr. WIGNER, Dr. MUTER, Dr. STEVENSON, and Mr. HEHNER were among the most important, but some others contained valuable suggestions.

It is admitted on all sides that great benefit has resulted from the Act of 1875. The use of adulterants injurious to health has practically ceased, and fraudulent adulteration, although still common in respect to a few articles, has been reduced and made more dangerous to the trader. This is much to have attained, and naturally suggests the question, which occupied a prominent place at the Conference, Whether legislation having done so much, it may not, by increased stringency, be made to do more. If so, it is clearly a part of the public duty of the medical profession to promote an early reform. A full consideration of the matter cannot be attempted in a single article, but a few general remarks seem necessary, and ought not to be delayed.

In the first place it is an important defect in the present law that too much option is left to local authorities. To this defect we have recently drawn attention. The Local Government Board has power to compel sanitary authorities to appoint public analysts, but cannot compel them to find work for them, or pay them properly. It sometimes happens that a local authority obstinately refuses to carry the law into effect. Whether this be due to false economy, interested motives, or sheer stupidity, the effect on the public is the same. Analysts are appointed, but they analyse nothing, and fraudulent tradesmen have it all their own way, to the injury of their honest competitors in trade, as well as of the public. In this, and in several other respects, no blame attaches to the public analyst. It ought to be more generally understood that the analyst has no control over the collection of samples or the prosecution of tradesmen, and does not, in the great majority of cases, know the names of the vendors. His duty is limited to the analysis of the samples sent to him and to the framing of certificates based upon these analyses. If legal action follows, it is not undertaken at his instance. The insufficient and often injudicious collection of samples is the one chief cause of the survival of adulteration. The inspector is generally well known, and his visits are apt to be made at too long intervals and to too few shops to exercise a sufficient influence on the trader. When we add that the penalties on conviction are often ludicrously small, that all kinds of legal quibbles can be used successfully to escape them, and particularly that the analyst is tied to a form of certificate so narrow as sometimes to be quite inapplicable, it will not be thought wonderful that adulteration lingers in the land. One fact, moreover, seems now to be certain: no important help can be looked for from the general public. It is, we presume, well known that any individual can, for a small fee, and sometimes for no fee at all, procure an analysis of any article of food or drugs, provided he has complied with certain conditions intended for the protection of the trader, and that, without cost to himself, the fraudulent trader may thereby be punished. But, as might perhaps have been expected, the public will not take the necessary trouble, and this part of the Act has but little practical effect.

The question of standards, or, as they are more properly called, limits, of purity was keenly debated at the Conference, and very different opinions were expressed in regard

Digitized by Google

to them. It is most important, and unfortunately most difficult, in the case of milk, which is more frequently adulterated than any other article of food. If the analyst is of opinion that a sample of milk has been sophisticated, either by skimming or by the addition of water, the law compels him to state the amount of such sophistication. Genuine milk differs so much in composition, and is occasionally so very poor, that it is impossible to say in any given case how much cream has been removed, or how much water added. The analyst protects himself as far as possible by stating that "not less" than so much cream has been removed or water added, but unless he takes the very worst milk as his standard—the milk of some half-starved cow, quite unfit for food—he must sometimes run the risk of reporting milk as skimmed or watered which came straight from the cow. The difficulty here is due to the wording of the Act, and might, we think, be easily overcome. The law ought to fix a reasonable limit of strength for milk, as it does already for spirits, and the selling of milk below this strength ought to constitute an offence. It is urged against the fixation of such a limit that it would encourage dealers to skim or water their milk down to the limit. But unfortunately that encouragement is already afforded, and we do not see how it can be avoided. Every milkman knows the limits adopted by public analysts and by the chemists of Somerset House, and knows that as long as he keeps the solids, not fat, up to 8·5 per cent. and the fat to 2·5 per cent., he may skim and water as much as he likes. Somewhat higher limits than these might, we think, be prescribed by Act of Parliament without injustice, and the public would really gain. The milkman who sold a better milk would get a better price for it, and if he guaranteed a certain quality, would of course be judged by that guarantee. Many other important points press for notice, but we must for the present leave them unconsidered.

THE slow rate at which the cholera epidemic progresses gives some hope that the outbreak may, after all, be more limited in character than was the case when Marseilles was last attacked. Both at Toulon and Marseilles the daily number of deaths has been much the same as during the previous week, and some additional towns have been attacked, the most marked importation having taken place at Arles; but, notwithstanding occasional rumours to the contrary, Paris seems not yet to have suffered from any appearance of the Asiatic disease. When the extreme heat which has prevailed is taken into consideration, this result may be regarded as hopeful; and it is by no means impossible that the reduction of temperature which has commenced may tend still further to limit the course of the epidemic. Extreme watchfulness is, however, still needed. The *St. Dunstan*, which arrived a few days ago in the Mersey, had had two deaths from cholera amongst her crew, and after keeping the remainder under observation for a day it was found desirable by Dr. TAYLOR, the medical officer of health for the Port of Liverpool, to remove seven others to the port sanitary hospital near Bromborough, Dr. HOPE, the assistant medical officer remaining in charge. The vessel was then thoroughly disinfected by means of carbolic acid, the ballast water was pumped into the river, and so far no further harm has happened.

Two curious instances of so-called preventive measures in countries where our system of inspection and isolation is not resorted to come under our notice together. In one instance the news is from Geneva, where impecunious people get into the train, and having given passengers an exaggerated account of the process of disinfection they will have to go through they exchange tickets, and for a substantial consideration they undergo the fumigation discomforts instead of the genuine travellers. The other comes in the form of a protest from the passengers of the homeward bound steamer *Mira* from Calcutta. Before touching at Colombo, on April 21st, one of the crew died of cholera. All necessary precautions having been taken the vessel reached Suez, and though sixteen days had elapsed, and all on board remained well, she was ordered to El Tor to perform seven days' quarantine. No proper arrangements had been made for their reception, and a few wooden huts with some disgustingly offensive privies afforded the only accommodation available for a large number of first-class passengers of both sexes. Such an arrangement is discreditable in the extreme to the Sanitary Council of Alexandria. But what follows is worse than discreditable. The death had occurred amongst the crew, who occupied an entirely distinct part of the ship to that which was reserved for passengers. And yet it was the passengers who were thus compelled to leave the ship and to go into quarantine, the crew being allowed to remain on board. Nothing but utter ignorance of the etiology of cholera can account for such a system.

Annotations.

"Ne quid nimis."

AN ENGLISH CHOLERA COMMISSION.

WE are enabled to state that the Government have directed Dr. Klein, F.R.S., and Dr. Heneage Gibbes, to proceed forthwith to India to pursue a scientific inquiry into the nature of cholera. It is understood that these gentlemen will act in conjunction with the Commission nominated a few weeks ago by the Indian Government for the same object. In the prosecution of their labours Drs. Klein and Gibbes may be assured of the hearty good wishes of all Englishmen, and the results of their mission will be awaited with great interest. The Government in arriving at this decision have only done that which ought to have been done twelve months ago; and it cannot fail to touch the national pride that the country which has the largest interest in arriving at a sound conclusion upon the nature of this disease should have allowed Germany and France to have preceded it in the research. It is better, however, to be late in the field than to ignore the value of such an inquiry altogether.

HOSPITAL FETE AT THE HEALTH EXHIBITION.

THE grand *fête* which was held under Royal auspices at the Health Exhibition on Wednesday evening last was not only in itself a brilliant success, but seems likely as its result to supplement the Hospital Sunday and Saturday Funds by several thousand pounds. It was at the kindly suggestion of the Prince of Wales that one of the two reserved Wednesday evenings was devoted to the benefit of the London hospitals, and, according to promise, his Royal Highness and the Princess of Wales honoured the occasion by their presence. The invitation which had been issued to the public to contribute flowers and fruit for sale during the evening

Digitized by Google

was promptly and most generously responded to. As a consequence there were no less than twelve stalls picturesquely scattered in various nooks and corners of the Exhibition buildings. Many of the stalls presented the appearance of a complete arbour of flowers, and the fair stall-holders were evidently doing a capital business; indeed it was impossible to resist such pleading as, "I don't sell roses every day—and, think, it is for the hospitals." The working dairies were specially decorated, their counters being covered with flowers and fruit, in addition to which milk, cream, butter, &c., were here sold. In connexion with this it should be mentioned that exhibitors at whose stalls articles were sold devoted the profits to the hospital fund; and Messrs. Bertram and Roberts, the refreshment contractors, contributed out of their takings a sum of £100. Twenty-six large firms also sent a liberal supply of flowers and plants. Eight bands of music performed in different parts of the Exhibition. The illuminations in the Horticultural Gardens were on an unprecedented scale, and afforded the prettiest imaginable sight. Everyone connected with the undertaking must have worked hard to secure its success, which was indubitable. If exception could be taken to anything, it was to an element beyond human control—the weather,—the evening being somewhat chilly, and dark clouds at one time threatening to spoil what was a veritable glimpse of fairyland.

THE WOUNDED POLICEMEN.

FOR the following notes on the cases of the two police constables who were shot last week at Hoxton in an encounter with burglars we are indebted to Mr. Toller, house-surgeon at St. Bartholomew's Hospital:—

David Garner and William Snell were admitted into St. Bartholomew's Hospital, under the care of Mr. Morrant Baker, on Friday morning, July 18th, the former suffering from a bullet wound of the thigh, and the latter of the abdomen. In the first case the bullet had passed through the back of the thigh, penetrating the hamstring muscles, the aperture of entrance being situated about the level of the apex of Scarpa's triangle and three inches to the inner side of the femoral vessels; passing behind them, it found exit in the middle of the back of the thigh, nearly four inches below the gluteal fold. The wounds presented the usual appearance, with the exception of the wound of exit, which seemed smaller and very ragged. The hæmorrhage was free at first, but soon ceased, and has not again given trouble. Sanitas oil dressings (1 in 30) were immediately applied, a small portion of which sealed the wounds, and were not frequently changed. The constitutional symptoms and the local trouble are very slight, and up to the present the parts are looking quiet. The case of Constable Snell is much more grave—rather from the possible consequences, however, than from any present symptoms of danger. The bullet in this case entering close to the outer border of the right rectus abdominis, and slightly below the level of the lower costal cartilages, appeared about an inch and a half to the right of the spinous process of the third lumbar vertebra. No sign in the shape of superficial tenderness or bruising in the abdominal wall from the track of the bullet could be discovered, although there was much ecchymosis and tenderness around the wound of entrance. The symptoms on admission (four hours after the injury) were severe. There was considerable prostration; the aspect was pinky and of a yellow colour, as of a man suffering from shock. The pulse was 99, of fair volume; temperature 99·4° F. The hands were somewhat tremulous, and the patient complained of pain in the back and abdomen. The temperature so far has not risen above 101·4°, and is now gradually descending. The bowels act without pain, the urine is natural, and there are none of the symptoms of peritonitis or pleurisy. The treatment adopted was similar to that in Garner's case, the wounds being sealed with sanitas oil lint (1 in 30), opium was administered occasionally for the first forty-eight hours, and the diet limited to fluids, with a small quantity of brandy. The revolver was a six-chambered one, rifled; and the bullets were conical, about half the size of a Martini rifle bullet. From the appearance of the wound and the absence of any superficial tenderness or bruising, and the constitutional symptoms at the time of the man's admission into the hospital, Mr. Morrant Baker is of opinion that the bullet probably passed through the abdominal cavity. Assuming that no important blood-vessel was wounded, and that the track made by the bullet was a clean one, there is every reason to believe that the patient will recover. From the position of the wound it is difficult to imagine that the liver can have escaped altogether; it seems most likely that the track of the bullet lies somewhere about or on its diaphragmatic surface, or its course may have been deflected by the diaphragm. In the absence, however, of any leading symptom, any statement regarding the exact position of the track can only be guesswork.

HEALTH RESORTS AT HOME.

THE season of "change" is again upon us, and "where to go" is the question of the hour. Practically, and as we think *prudently*, the Continent is regarded as closed against visitors for the present year. There is no cause for regret on this score. No climate, no waters, no baths, no air, can be obtained or enjoyed on the Continent for the "cure" of any disease whatsoever—we say this advisedly—which cannot be obtained in as great, or even greater, efficiency within the limits of our own islands. For example, Strathpeffer, in Scotland, is incomparably better, so far as remedial resources are concerned, than Royat or Ems, or any other of the vaunted spas or baths across the "silver streak." Buxton, Matlock Bath, and a score of other places, are every bit as good as the health resorts to which it is *fashionable* to go at great personal trouble, and risk of contamination by dirt or blood-poisoning from the insanitary condition generally of the Continental places of concourse. It is simply because a long journey must be taken, and the language spoken is different, and because the local authorities of these places abroad are wiser in their generation than our local authorities at home, and spend more money to make their surroundings attractive, that foreign baths and spas are popular. We cannot hold the members of our own profession free from blame in the matter of crying up the "waters" and "baths" of the Continent at the expense of those of the home country. Let us hope that this year pains will be taken to search out and form a just and patriotic estimate of the facilities for *change* and recuperation which lie so close at hand that we almost systematically neglect them.

THE TREATMENT OF COMPOUND FRACTURES.

A PAPER of much practical interest was read by Dr. Fred. S. Dennis, Professor of Surgery in Belle Vue Hospital, &c., New York, at the recent meeting of the American Medical Association. Professor Dennis does not disparage the antiseptic principle in the surgery of compound fractures, but he is eminently an advocate for the adoption of cleanliness. The success of his practice will be apparent when we say that, after excluding deaths from shock &c. within forty-eight hours after admission, he is able to report 100 cases of compound fracture without a death from any cause. They are divided into cases of—1. Compound fracture of the skull: of these there were 23 cases; excluding 6, there remain 17 cases of recovery from compound fracture of the skull, in succession, with no death, 10 of which required

Digitized by Google

trephining. 2. Compound fracture of the thigh: all of these recovered; in one amputation was required. 3. Compound fracture of the leg: of these there were 58; all the patients recovered except 2, who died from shock within forty-eight hours. Ten of the cases opened into the knee and ankle-joints. In a few the hæmorrhage was formidable. One case was a double compound fracture of both bones of the legs with alarming hæmorrhage, but the patient was out of bed and sitting in a chair on the fourteenth day without a bad symptom. Amputation was practised in 11 of these cases, generally primary; all recovered. 4. Compound fracture of the arm: 12 cases, all of a serious character, and all recovered. 5. Compound fracture of the forearm: 14 cases; all recovered but one, which was complicated with extensive burns, the patient dying of shock within twenty-four hours; of the remaining 13 cases, 3 opened into the wrist-joint and 1 into the elbow-joint. 6. Compound fractures of the jaw: all recovered. Professor Dennis says: "Deducting cases of compound fracture of the hand and foot, 14 cases of primary amputations, and 9 deaths from shock, there remain 100 consecutive and of course unselected cases, occurring in three hospitals, without a death." We congratulate Dr. Dennis on a record so creditable. The points of his treatment are (1st) absolute cleanliness; (2nd) immediate fixation; and (3rd) provision for free drainage when necessary. The patient is generally anæsthetised, and the injured part washed with soap and water, and "scrubbed well with a brush," so as to remove débris, dirt, &c. The limb is then irrigated for a few moments with a 1-40 solution of carbolic acid, or 1-2000 solution of corrosive sublimate. Care is taken to replace broken fragments, or, if necessary, to remove projecting ends. When these cannot be reduced without much violence, Dr. Dennis divides tendons subcutaneously to overcome resistance and secure muscular rest. The results speak for themselves. The details of Listerism are not practised, but its principles are not ignored; and Dr. Dennis's cases go essentially to swell the triumphs of careful cleanly surgery. The paper, with tables and temperature charts, will be found in the Journal of the American Medical Association for June 21st.

SMALL-POX AT KIMBERLEY.

IN a leading article of May 10th, 1884, whilst discussing the nature of the epidemic that had broken out in the Diamond Fields in the autumn of 1883, we used these words: "The peril to the Kimberley district has been removed for the time being, but for divers reasons it may at any moment 'develop dangerous energy.'" One ground for fearing what has since happened was the resolute denial by Drs. Jameson and Wolff that the disease was small-pox. No doubt these gentlemen recognised, as the merest tyro could not fail to do, the deadly nature of the visitation; at the same time the general public are guided in their action by the position taken by their medical advisers, and the more so when the latter are men of considerable attainments and known ability. Again, there is much in a name to stimulate to action or induce an indolent repose. Can it be denied that if the members of the French Academy of Medicine had persisted in calling the present outbreak at Marseilles and Toulon "cholera nostras," the number of victims would have been much greater. It is to be regretted that Drs. Jameson and Wolff did not see the mistake they had made, or seeing, that they did not acknowledge it. At last the local authorities of Kimberley and adjoining districts, assisted by the central executive, have awakened to a responsibility of their position. A lazaretto has been established at Dutoitspan for the reception and detention of persons suffering from the contagious disorder, which we have no hesitation in calling small-pox. Dr. Saunders, the Special Cape Town Commissioner, has reported himself satisfied with the arrangements by which Dr. Jameson is reported to have said he will "stamp out the disease in three weeks." We sincerely trust the prediction may be fulfilled; the best guarantee that it will be would be the avowal by Drs. Jameson and Wolff that their theories of "varicella" and "pemphigus" no longer hold water, whatever the vesicles and bullæ may contain. With other correspondence, we have received a printed copy of the short-hand writer's report of the cross-examination of Dr. Jameson at the late trial of Dr. Wolff for having contravened the provisions of the Public Health Act, 1883, and also photographs of two cases diagnosed by Drs. Jameson and Wolff as chicken-pox. The former will be read with amazement by those who give it an unbiased consideration; the latter would form an excellent illustration of a description of small-pox, and one worthy a place in our leading text-books.

POST-MORTEM DIFFUSION OF ARSENIC.

DRS. VAUGHAN and DAWSON, of the University of Michigan, U.S.A., have recently conducted some important experiments with the view of ascertaining if arsenious acid injected into the mouth or rectum after death would diffuse through the body. These observers not only found that such was the case, but that the diffusion was very extensive. The results of their investigations have a very important bearing on the question of arsenical poisoning. In the first place, it can no longer be contended that because arsenic is found in quantity in the fluids and tissues of the body, that therefore death was due to its administration; and in the second, a certain amount of immunity is given to the would-be murderer, inasmuch as there is the possibility of covering a homicidal act by using arsenic with the ostensible purpose of preserving or embalming the body. We say possibility, for such a procedure would almost to a certainty be defeated in its aim. At any rate, there would be no chance of success if the post-mortem examination were conducted within a short time of death, when there would be the usual signs of inflammatory action in the alimentary canal; and again, in the face of other circumstantial evidence, the fact of the accused having resorted to such a particular mode of preserving the body would rather tend to confirm suspicion than to remove it. That arsenic contained in soil may be dissolved in water and conveyed into the body has long been known. The researches of Drs. Vaughan and Dawson show what appears *a priori* as probable. During decomposition the relative humidity of different parts of the body, and of these with surrounding media, is constantly changing. Interstitial currents are passing through the tissues by osmotic action, and this liquid diffusion is naturally increased by the presence of crystalloid substances in solution; nor does it cease until the dialysis ends in an equilibrium of attraction which one fluid has for another, or presumably until post-mortem disintegration is complete.

SCHOOL HYGIENE AND OVER-PRESSURE.

THE Medical Society of London and the National Health Society are about to hold a series of very important conferences at the Health Exhibition next week. On Monday the subject of school dietaries will be discussed; Dr. de Chaumont is announced to read a paper, and Sir Andrew Clark, who presides, may be confidently expected to have much to say on this subject, upon which he can speak with great authority. The most important of the entire series of conferences, however, is that to be held on Tuesday, when the question of over-pressure in schools will be dealt with. Great pains to approach this subject in a definite and practical form seems to have been taken, and four propositions

Digitized by Google

will be submitted to the meeting by men so well versed in the matter as Mr. Pridgin Teale, Dr. Crichton Browne, Sir Joseph Fayrer, Mr. Brudenell Carter, and Mr. Marchant Williams. Mr. Kegan Paul is to open the discussion on the other side, and in his hands the case of the educationalists is eminently safe; and already Sir Andrew Clark, Dr. Michael Foster, Dr. Gladstone, Dr. Farquharson, and others have announced their intention of taking part in the discussion. This subject is one of immense importance, and has been well chosen for debate at such a Conference. On Wednesday the questions in relation to the prevention and treatment of Infectious Diseases will be discussed, and Dr. G. Buchanan is to preside. Thursday will be devoted to a discussion on School Construction and Arrangements. On Friday Sir James Paget will preside at a discussion on Recreations and Gymnastics, and on Saturday the series will be concluded by a Conference on the needful requirements of institutions for the education of idiots, foundlings, rickety and scrofulous children, &c., at which Dr. Langdon Down is to preside.

"THE IMMORTALITY OF LIFE."

No change can be effected without a number of disturbances. The disturbances may be classifiable, and are for the most part of very different sort. If a certain statement be made there is no question but that many authors will come forward with other declarations, each assertion having more or less relationship to the statement of the original author. When bacteria were first seen and described as living organisms of a microscopic nature, views were not wanting that these bacteria were merely crystals or pieces of fibrin or dirt, or some other substance having some likeness to the alleged micro-organisms. Amongst the many revelations which were thus brought to light in accordance with this law of bye-products was an assertion by Dr. Rollin Gregg that bacilli were neither more nor less than particles of fibrin. The gentleman just named has not finished exercising his ingenuity in this field of research. The "Revelations of Fibrin," "Unexpected Proof of the Immortality of Life," serve as the startling titles to a fresh literary attempt of the enthusiastic author. The accidental occurrence which is brought forward to prove that life is imperishable was provided by experiments of the following nature, as detailed in the *Buffalo Courier*. If some fresh fibrin taken from any source be placed in distilled water and allowed plenty of time to rot, abundance of rods endowed with remarkable powers of motility are said to appear. So far the author merely states what no doubt actually takes place. But there are many ways of describing facts. Unfortunately in the transcription there is a great tendency to the introduction of inferences not wholly of a legitimate kind. Dr. Gregg professes to believe that in the crude process above-mentioned the moving particles are merely animated filaments of fibrin. It is on these grounds that the "immortality of life" is established. There seems to be not a little ambiguity in this phrase just quoted. But let us take it as meaning that there is no such thing or quality as death, and examine it from that point of view. Physicists have taught that neither matter nor force is capable of destruction, and if by death is meant an utter annihilation, then probably all things and qualities live in some form or other. But see where such speculations land us. Words are made conventionally to have definite meanings, and truly, if we go the length of our above temporary hypothesis we may be said to have knocked all the sense out of our terms. Dr. Gregg ought to be aware that his views are simply a repetition of the doctrines of spontaneous generation, and consequently are to be met by the same sort of refutations as have been brought against the teachings of generation *de novo*. Heterogenesis is the term Dr. Bastian would apply to the process by which Dr. Gregg's revivified filaments of fibrin were provided. On this gentleman's showing the bacillus of tubercle or that of cholera may arise in a dish of rotting fibrin. The reason why the bacillus of cholera, which is merely a shred of animated fibrin, does not stain with dye is because its substance has not been softened by a suppurating process like that to which the bacillus of tubercle is exposed!

THE WASTE OF THE MEDICAL PROFESSION.

AMONG the many fallacies with which Sir Lyon Playfair's speech on the second reading of the Medical Acts Amendment Bill abounded, perhaps the greatest was his statement as to what he called the waste of the profession. This was so serious that he owes it to the House of Commons either to confirm or to correct it. He said the doors of the profession must be wide enough to admit 1600 men annually, which is the waste of the profession, and he drew a startling picture of the risk of depriving the country of doctors by pitching the examinations too high. Will Sir Lyon Playfair tell us what reason he has for stating without hesitation in the House that the waste of the profession is 1600 men? The Medical Register should be some authority on that point. The Medical Registrar is a careful man, and he is supposed to have the best information as to the deaths of registered practitioners. Registrars of deaths are bound by Act of Parliament to send him notice of all deaths of registered persons. Besides, his credit is at stake in being fairly accurate in his statistics. From these statistics we gather that the number of deaths of registered medical men—in other words, the waste of the profession—is between five and six hundred. In the last three years, 1881, 1882, and 1883 respectively, it was, according to the Register, 526, 522, and 530. Here, then, is a discrepancy of more than a thousand between the official Register and Sir Lyon's statement. The numbers of deaths in the Register may not, and doubtless do not, represent the entire deaths or waste of the profession. But it is inconceivable that the official roll is not much nearer the mark than Sir Lyon Playfair, whose great argument thus falls to the ground. Besides, the Register shows a steady increase in the number of persons registering annually. Thus, in 1881, 1053 persons registered; in 1882, 1171; and in 1883, 1304—an increase which is confirmed by the competition in the profession and the obvious excess of practitioners in most places.

CHOREA AS A COMPLICATION OF PLEURISY.

A FEW years ago several cases of fatal epileptiform seizures following upon intra-pleural injections in empyema were recorded, especially in France. The subject has again been brought under notice by Dr. Weill of Lyons, who records a case where hemichorea was apparently excited in the same way (*Revue de Médecine*, July, 1884). A young man twenty-four years of age, whilst on military service was attacked with left-sided pleurisy, for which paracentesis was performed. Empyema followed, necessitating drainage and injections, and it was noticed that the left arm became weak immediately after the operation. A year later a second operation was performed, and six months afterwards M. Lépine, under whose care the patient was, deemed it necessary to have portions of the second, third, fourth, and fifth ribs resected. Two days after this operation the left upper limb became the seat of involuntary movements, and shortly after the left lower limb also. These movements were of a choreic character, and were associated with some hyperæsthesia of the hand and a certain degree of ataxy in the lower limb. The condition was attributed to the pleural irritation produced by the antiseptic injections

Digitized by Google

acting on the spinal cord, and thence affecting in a reflex manner the limbs of the same side. This idea of reflex irritation proposed by M. Lépine seems to M. Weill a very reasonable hypothesis, and it would appear as if there were functional and pathological connexions between the innervation of the pleura and that of the limbs of the same side, especially of the upper limb. The occurrence of radiating pain in angina pectoris, and of the shoulder pain in hepatic colic, are instances of a similar kind; and the fact that besides the severe and fatal convulsions excited by intrapleural injections, there have also been recorded numerous instances of hemiplegia associated with like pleural conditions, justifies the notion that in the present case there is an example of chorea excited by the same path.

DENTAL SURGERY AT CAMBRIDGE.

A MEETING has been held at Cambridge of the Eastern Counties Branch of the British Dental Association, and the respective authorities granted the use of Merton Hall and the old anatomy theatre in the University for the various meetings. A dinner was held on the second evening in the Hall of Downing College, and Professor Humphry responded to the toast of the University of Cambridge. He said that the University and the town were glad to welcome the representatives of the dental profession and of an association for the advancement of science and the benefit of mankind. He referred to a practical point, the need of a dental surgeon on the staff of Addenbrooke's Hospital, and thought the governors would soon appoint one or more dental surgeons, and this would be a great benefit to the hospital and to the medical students. Professor Humphry also said that the Dentists Act had given a great deal of trouble to himself and his colleagues on the Medical Council. Several of the clauses were ambiguous, and, as there was a doubt, it had been found necessary to give a number of persons the benefit of the doubt, in spite of the protests of the Association. Notwithstanding these difficulties, which time would efface, Professor Humphry believed that the Dentists Act would prove of the greatest benefit to the public and the profession. He thought there could be no doubt that dental science and practice had made great advances even in the short time which had elapsed since the passing of the Act.

ELIMINATION OF IODIDE OF POTASSIUM.

A CAREFUL investigation into the modes and rate of elimination of so valuable a therapeutical agent as iodide of potassium cannot fail to be of interest, though the investigation may not be entirely novel. M. Desprez has made numerous analyses bearing on the subject, under the guidance of M. Lépine. The following facts have been ascertained by him. If a subcutaneous injection of four centigrammes of iodide of potassium be made in a healthy individual, the urine will be found to contain two-thirds, and sometimes more, of the salt injected. The urine passed twenty minutes after the injection always contains an appreciable quantity of iodide. The elimination by this path continues for forty-four hours. The rate of discharge sometimes decreases in a very regular manner, but frequently, and especially towards the end of the excretion, there is irregularity; so much so that at times the urine may be free from the salt, only to be followed by a period in which the iodide again makes its appearance. After the injection under the skin of nine centigrammes of iodide one-half the salt may be recovered in the urine. It appears to take but three hours longer for the larger quantity of the salt to be totally eliminated. The presence of fever does not have any influence as regards the quantity of the salt discharged, but it prolongs the duration of the process. If fever is accompanied by renal mischief, the quantity of the salt eliminated is lessened, and the time taken is diminished. In cases of cardiac weakness not associated with renal changes the elimination is greatly prolonged, though the amount ejected may remain the same. But if renal complication be added to the above conditions a less quantity is excreted. In Bright's disease the iodide takes some time to appear in the urine; the quantity eliminated may be reduced to a fourth, a fifth, or even an eighth, and, speaking generally, the time required for total elimination is longer.

THE INCREASED MORTALITY IN ENGLISH TOWNS.

THE Registrar-General's recent weekly returns show that the annual death-rate in twenty-eight of the largest English towns, with an aggregate population of nearly nine million of persons, which had averaged only 19·4 in the five weeks ending the 5th inst. (ranging from 18·7 to 19·8), rose successively to 22·2 and 24·0 in the two weeks ending 12th and 19th inst. These figures signify an excess of 1255 deaths in the twenty-eight towns during the past two weeks. Two simple facts will show how this increase was caused. The deaths attributed to diarrhœa in these towns during the past two weeks exceeded by 1163 the number that would have been recorded had they corresponded with the average number in the five preceding weeks. Moreover, the deaths from all causes of infants under one year of age, which had averaged 758 in the five weeks under notice, were 2913 in the two weeks ending the 19th instant. It appears, therefore that more than the entire increase of deaths in these twenty-eight large towns occurred among infants under one year of age, and that nearly the whole of the increase was referred to the heading "diarrhœa." The annual death-rate from diarrhœa in these towns, which had averaged 1·0 and 3·0 per 1000 in the first two weeks of July, further rose to 5·0 in the week ending the 19th inst. No death was attributed to diarrhœa last week, either in Brighton, Wolverhampton, or Plymouth; whereas the recorded deaths from this cause were equal to an annual rate of 5·8 per 1000 in Salford, 6·4 in Leeds, 6·6 in Nottingham, 6·8 in Preston, 6·9 in London, and 12·2 in Leicester. It will be noted that most of these towns are the same in which are recorded, year after year, the greatest waste of infant life from all causes as well as from summer diarrhœa fatality. It is still a grave problem how much of this mortality from infantile diarrhœa is directly due to causes within the control of sanitary authorities, and affecting what is generally understood by "sanitary condition"; but it can scarcely be disputed that very much of this waste of infant life is distinctly preventable by human agency, sanitary and social, and that its annual recurrence is the result of apathy and neglect.

HIGHBURY FIELDS.

THE action of the Islington Vestry in unanimously agreeing to advance half the reasonable cost of buying Highbury Fields, on the condition that the Metropolitan Board of Works advance the other half, has given great satisfaction not only in the immediate neighbourhood, but generally in the metropolis. The extension of London is an overwhelming problem. One thing is clear that if sanitary disaster is to be averted and life is to be at all tolerable among its millions of toilers, open spaces such as that of Highbury must be maintained. The vestry of Islington is entitled to much credit for this action, and we heartily trust that the Metropolitan Board of Works will show equal regard for the interests and the health of this populous and important district of London.

EVASION OF THE VACCINATION ACT IN DEWSBURY.

THE Solicitor-General, a few days ago, brought an action on behalf of the Local Government Board against the Guardians of Dewsbury Union, in respect of their refusal to appoint public vaccinators for two districts under their charge. The offices in question were vacant a year ago; the guardians, disapproving of vaccination, neglected to fill them and received a request from the Board to discharge this duty. After a time vaccinators were reluctantly advertised for, applications were received and refused, and advertisement began again. On July 4th a last motion for the appointment of vaccinators was rejected, and the majority found courage to resolve that the letter of the Government Board "lie on the table," though even now their faint heart would accept a committee of inquiry. It should be noted that in their diplomatic opposition the guardians, like some others who think with them, did not act for themselves, but they denied a benefit to persons practically helpless who were committed to their care. The Court of Queen's Bench had of course no difficulty in supporting the Local Government Board in its demand. The subject which this case opens up is a large one, and we cannot in a single article cover it in all its bearings. This much is certain, that, under the influence of vaccination, small-pox, which once was justly dreaded like the plague, has become a languid and comparatively tolerable evil, and has greatly lost its epidemic character. It still remains among us, chiefly because evasions like those of the Dewsbury guardians have maintained a soil for its development. Further, in the presence of such evasion, we must emphatically assert that vaccination has brought with it no inherent evil or risk whatever. Cases of illness after it, as is well known, are rare in any class, though less so among the poor than the rich. Occurring after, they are apt to be ascribed to vaccination, to which they are not properly referable. Yet these have most unjustly been made the ground of much emotional opposition to its practice. Uncleanly habits, neglect, concurrent illnesses quite alien to small-pox or vaccinia, may have introduced accidental maladies, even though but seldom, yet this does not mar the value of vaccination or lessen the need for it. With as much, nay, with much more, reason might the railway or the street vehicle, with every branch of art and manufacture, be condemned to extinction. For vaccination, as for each of these, one cause, necessity, exists. So long as it exists they must continue; and accident must be met by care and forethought, not by blind denial of that necessity.

NURSES FOR THE SICK POOR.

ON the auspicious occasion of the opening of the new nurses' home attached to the St. Marylebone Infirmary by H.R.H. the Princess Christian, we were kindly invited by the indefatigable and able medical superintendent, Mr. J. R. Lunn, to make an inspection of the whole of the magnificent buildings which are situate in an open and airy space within the view of all who leave town by the Paddington Station. We can testify to the curiosity which has been excited in the minds of uninitiated passengers on the Great Western Railway as to what the conspicuous pavilioned edifice might be. Whatever admiration may be called forth by a glimpse of the exterior of this hospital for the sick poor, that admiration suffers no diminution by a careful inspection of the interior and *personnel* of the noble institution. Contrasted with the disgraceful state of affairs revealed by THE LANCET Commissioners prior to the Gathorne Hardy Act of 1867, it is no exaggeration to say that this infirmary is a perfect paradise, not only to our pauper fellow subjects, but also to those who have laboured in the field of Poor-law reform. The main object of the erection of the neat and excellent building on the south side of the infirmary is to provide accommodation for forty nurses and probationers. A separate bedroom has been allotted to each person, and we cannot praise too much the good taste and common sense which have guided the planning out of the domestic offices and other apartments of this model home for nurses. The guardians of the infirmary and Mr. Lunn deserve much commendation for their determination to provide this and kindred institutions with the means for the supply of a succession of well-trained nurses, and the council of the Nightingale fund have done well by co-operating in this good work. So much for the nursing of the sick and infirm paupers. But one other thought has suggested itself, though not for the first time, and that is the possibility of utilising in some measure the advantages which offer themselves in our infirmaries for the instruction of medical students. Here, in these institutions, is a collective mass of clinical and pathological material which it is not unfair or unwise to say cannot be made proper use of by the customary medical authorities of these sick populations.

THE VOLUNTEER HOSPITAL CORPS.

DURING the past fortnight the medical students who form this corps have shown themselves in considerable numbers in different parts. They have paraded twice, first in a battalion and then as a company, at Wimbledon Camp. In Hyde-park and at the Health Exhibition the public have had an opportunity of seeing the kind of work meant to be done. On Friday last the corps paraded before the Princess Louise and the Marquis of Lorne in St. George's Barracks, Trafalgar-square. The students to the number of seventy rank and file, besides officers, appeared in uniform, the same as that worn by the Army Hospital Corps. There are now about 350 men in the different hospitals who have been trained, but the process of getting into uniform is slow owing to each man having to provide his own. The proficiency of the corps is excellent, and under the command of Mr. Cantlie, with Dr. Squire as adjutant, the corps handles well.

TREATMENT OF NASAL POLYPUS.

DR. RICHARDSON, in the *Asclepiad*, recommends the use of sodium ethylate in the treatment of nasal polypus. The caustic agent is applied by means of a probe made of soft cotton-wool twisted into shape on the points of a pair of forceps. This cotton probe is saturated with the ethylate and then plunged into the substance of the polypus. On removing the cotton it commonly happens that the patient can expel the whole mass of destroyed polypus, in a semi-fluid form, by blowing the nose sharply. A second application ought to be made with a view of destroying the base of the polypus. The mode of action is said to be sufficiently clear. The ethylate is decomposed by contact with the water of the polypus into caustic soda and alcohol; the latter coagulates the albuminoids and the former acts as a powerful caustic. With the exception of some burning pain no unpleasant effects seem to follow the use of this method.

INDIAN BARK.

FROM an official statement of the trade of British India it appears that the exportation of drugs has doubled during the last five years. This increase is due to the development of trade in cinchona bark. Madras contributed most largely to swell the exports, the cultivation of cinchona in that presidency being more extensively carried on in private estates than in Bengal, where the principal "bark" estates are the property of the Government, which reserves a large

Digitized by Google

proportion of the bark produced for the local manufacture of the alkaloid. [Most of the bark hitherto exported has come to London, but the demand from Italy for Indian bark is increasing. The local manufacture of the alkaloid above referred to is seriously affecting the import of quinine from Europe into India. It is believed that in time the supply of quinine from Darjeeling and the Nilgherries will meet all the wants of the Indian population.

THE DARENTH SMALL-POX CAMP LAWSUIT.

A LAWSUIT which bids fair to be one of extreme importance, and which may settle some, at least, of the points in dispute as to the influence of small-pox hospitals on the neighbourhoods in which they are situated, has entered on its first stage. The Metropolitan Asylums Board have, as is now well known, established two large camps at Darenth for the reception of a thousand convalescent and mild cases of small-pox, and these camps are about 700 yards distant from the estate and residence of Mr. Thomas Horn Fleet, who seeks for an injunction to restrain the Asylums Board from maintaining the camps there. The plaintiff alleges nuisance, the possibility of infection being conveyed as far as his house, and also injury to his property. The defendants, on the other hand, bring forward evidence to show that it would be impossible for small-pox to be conveyed through the air from the camp to Mr. Fleet's residence. The case having been partially heard, Mr. Justice Pearson explained that since it would be impossible, under any circumstances, to order the removal of the patients until ample time had been given for the preparation of other accommodation, no good would result from hearing the case for an interim injunction at this stage, and it was therefore ordered to stand over until it was fully ready for a hearing. If necessary, he added, the pleadings could be continued during the vacation. The trial, however, has been adjourned until November. This result is by no means to be regretted, for in the interests of science it is very important that the evidence to be brought forward on both sides should be very carefully selected. The opinions expressed before the Hospitals Commission as to the distance at which the small-pox poison could be conveyed aerially varied so widely as to show clearly that but little is as yet known on the subject. Indeed, we have reason to believe that Mr. Power's investigations are the only ones which have been carried out with strict scientific accuracy, and possibly his renewed labours may throw new light on this subject before the trial commences.

THE BRITISH MEDICAL ASSOCIATION.

THE fifty-second annual meeting of the British Medical Association will be held at Belfast on Tuesday next and the three following days. The President elect is Dr. James Cuming, Professor of Medicine in Queen's College, and physician to the Royal Hospital, Belfast. Dr. William Ord will deliver an address in Medicine on Wednesday, July 30th, Dr. Peter Redfern an address in Physiology on the following day, and Dr. G. H. Kidd an address in Obstetrics on Friday. There will be no address in Surgery. As usual, the proceedings will be diversified by excursions to various places of repute, in which the locality abounds.

BACTERIAL URETHRITIS.

THE number of varieties of inflammation of the urethra cannot properly be regarded as less than the number of inflammations of any other mucous surface. It has long been recognised by surgeons that intense urethritis is not necessarily of gonorrhœal nature. Neisser and others have described a micrococcus as the cause of gonorrhœa. Aubert has for some time past made a systematic examination of urethral discharges, and in three instances has found, instead of the gonococcus, a rod-shaped micro-organism. He has traced a resemblance between these bacteria and those found in pus from ulcerative balanitis. Although Aubert is inclined to regard the presence of the bacilli as indicating a different variety of urethritis, he wisely abstains from giving his positive adhesion to this view.

THE HOSPITAL SUNDAY FUND.

THE Distribution Committee is summoned to meet at the Mansion House on the 31st inst. The total amount available for distribution, after allowing sufficient for liabilities and the usual current expenses, is £31,283. Of this sum £29,026 is recommended to be apportioned to ninety-eight hospitals, and £2257 to fifty dispensaries.

OLEOMARGARINE.

WE have on previous occasions expressed our opinion in regard to the sale and use of substitutes for butter. The sale of such substances as genuine butter is a fraud, just as the selling of chicory under the name of coffee is a fraud. And the use of any disgusting or dangerous substance in the manufacture ought to be rigidly prohibited and severely punished. But much, at any rate, of the oleomargarine sold is merely purified animal fat incorporated with genuine butter. Such a mixture is better, as well as cheaper, than much of the common butter sold. If it were prohibited altogether, the price of butter would rise materially, to the great injury of the poorer classes. All that we contend for is that the public ought to know what they are buying and be prevented from buying anything noxious. — *The Lancet*.

ON the 18th inst., the students of Charing cross Hospital assembled in the Upper Lecture Theatre of the Medical School, in order to make a presentation to Mr. J. Cantlie, the popular sub-dean, on the occasion of his approaching marriage. Dr. Corbould, a former student, occupied the chair, and he was supported by Mr. Canton, who preceded Mr. Cantlie as demonstrator of anatomy to the school. The presentation included a silver punch bowl and ladles.

THE plague is reported to be still raging in Bagdad and its vicinity. In Badra, where the epidemic took its rise, the mortality from the disease is stated to be enormous; but it is difficult to get at the real facts, in consequence of the efforts of the authorities to maintain secrecy.

FROM the report on the composition and quality of daily samples of the water supplied to London for the month of June, recently issued by Messrs. Crookes, Odling, and Tidy, it appears that the supply differed but little in character from the supplies of the preceding months.

WE are glad to learn that the Academy of Medicine of Paris has, on the report of Dr. Brouardel, unanimously voted that quarantine on land is impracticable in France, and that the process of disinfection at present imposed upon travellers and their luggage is inefficacious.

A LECTURE on the Rearing of Hand-fed Infants will be given at the Health Exhibition on August 1st, at 5.30 P.M., by Mr. E. Owen, of the Hospital for Sick Children. The chair will be taken on the occasion by Dr. Charles West.

M. CLOSMADEUC has recently performed the Cæsarean operation successfully both for mother and child. This makes his third operation and third success.

Digitized by Google

THE introduction of a Bill for the Regulation of the Sale of Patent Medicines has been abandoned for the present session. A measure with the same object in view has, however, been prepared, and will, it is understood, be brought in by Lord Carlingford next year.

THE Select Committee on the Ventilation of the House of Commons held its first meeting on Wednesday. It is said that the evil odours which have recently annoyed honourable members have been traced to a factory in the vicinity of the House.

THE French Government has conferred the Order of the Legion of Honour upon Professor Koch, in recognition of his services in connexion with the investigation into the causes of the outbreak of cholera.

PROFESSOR ABBY of Berne has been appointed to the Anatomical Chair of the German Medical Faculty of the University of Prague, and Professor Strasser is named as his successor at Berne.

MR. HOPWOOD has blocked the second reading of a Bill brought in by Messrs. Gray and Dawson, "to make better provision against cholera and other dangerous epidemic diseases."

A VERY satisfactory report of the Jamaica Public Gardens and Plantations for the year ending September, 1883, has been drawn up by Mr. D. Morris, M.A., F.G.S., the director.

MR. VICTOR HORSLEY, F.R.C.S., has been appointed Professor Superintendent of the Brown Institution in succession to Dr. Roy.

THE second reading of the Canal Boats Act Amendment Bill will be moved by Lord Carrington in the House of Peers on the 28th inst.

M. CORNIL has been elected a member of the Académie de Médecine.

THE CHOLERA.

M. PAUL BERT has concluded his series of articles on cholera, and winds up his remarks as follows:—"We must give up supposed precautionary measures, which are merely troublesome without being of use. As soon as the first cases of cholera appear in any place we must take energetic steps to prevent contagion being transmitted by the discharges of the cholera patient and the objects used by him. We must consume none but perfectly cooked food, and take no beverages but those into which the germ of the disease cannot have penetrated or in which it has been destroyed by boiling. We must avoid all occupations which enfeeble the body, and especially all which may disturb the functions of the bowels. Finally, we must not yield to excessive fear of this disease, which, all things considered, is less terrible, less murderous, and far more accessible to the influence of remedies than the mysterious and subtle diphtheria." Last week there were in Paris thirty-seven deaths from choleriue and two deaths from sporadic cholera, the victims in the latter cases being men of seventy-five, one of whom had been drinking much iced beer and brandy while weakened by indigence and uncleanliness. At Toulon the Government has remitted the punishment of most of the prisoners in the civil prison, and out of 150 about forty only are now detained. The committee on M. Paul Bert's Cholera Bill was nominated on the 19th inst. Of the eleven members, all, except M. Paul Bert himself, were adverse to the Bill, which has since been withdrawn. Dr. Onimus has gone to Marseilles to study the epidemic there, and to make trial of a new mode of treatment—the administration of pulverised ozone.

At the meeting of the Academy of Medicine of Paris on the 22nd inst., a letter was read from Dr. Fauvel announcing that on regaining his health he will return to Paris and maintain against all comers that the epidemic is not Asiatic cholera. He urges that if the disease were contagious it would have established itself at Nimes, Lyons, and other towns, where there have been only isolated cases. Dr. Guérin read a long paper with a view of showing that the distinctions drawn between different forms of cholera are purely arbitrary, the malady differing merely in intensity, and argued that the simultaneous appearance of cases in parts of Toulon and Marseilles quite remote from each other was inconsistent with the theory of importation. On the 23rd inst. the Dispensary Committee at Cork held a special meeting, and instructions were issued to the medical staff, with a view to more vigorous action. A house-to-house examination was ordered, and additional sanitary officers were appointed. Mr. H. Le Cronier, medical inspector for the town of St. Heliers, has written to a contemporary to dispel the fears which have been expressed as to the cholera, owing to insufficient sanitary precautions, becoming prevalent in the Channel Islands. During the twenty-four hours ending at 8 P.M. on the 23rd inst. the number of deaths from the disease at Toulon was forty-four and at Marseilles sixty. The situation at Arles is stated to be even worse, and fresh cases are reported from Aix.

At a meeting of the City Commissioners of Sewers on the 22nd inst., Dr. Sedgwick Saunders, the medical officer of health for the City of London, presented a lengthy and exhaustive report on the subject of cholera. An order has been issued by the Local Government Board prohibiting the landing at any place in England or Wales of rags exported from Marseilles or Toulon.

A series of precautions against the infection of cholera, typhoid fever, &c., drawn up by Dr. Taaffe, medical officer of health, are being issued in large numbers by the sanitary authority of Brighton.

SALT IN CHOLERA.

In the House of Commons, on the 7th inst., Mr. Justin McCarthy asked the Under-Secretary of State for India whether, considering the alarm throughout Europe at the spread of Asiatic cholera, and in view of the statement that there is a deficiency of salt in the blood of those dying of Asiatic cholera, and that a sufficiency of salt is not now partaken of by vast numbers of the natives of India, due to the Government tax, Her Majesty's Government will abolish the salt tax in India. In THE LANCET of August 23rd, 1834, Mr. George Beaman recommended common table salt dissolved in water for the treatment of cholera patients, and reported that he had by this method successfully treated eleven consecutive cases. The good effect, Mr. Beaman stated, depends on powerful vomiting being produced; should vomiting not occur, a second or third dose is required at intervals of five minutes. If the beneficial effect is not permanent, another dose must be given in twenty minutes or half an hour. On April 21st, 1855, we published a letter by Dr. Beaman on the "Salt Monopoly in India, the alleged cause of Cholera"; and in the same year Dr. Beaman addressed to Lord Panmure, at that time Minister of War, a letter, a copy of which appears in our issue for April 28th of that year, in which he repeats his eulogy of salt in the treatment of cholera, and concludes by urging the abolition of the salt tax in India. The fifty years that have elapsed since Dr. Beaman first wrote have not added much in favour of his recommendation, and although there is probably a certain diminution in the saline ingredients as well as in the water of the blood, it is now generally recognised to be futile to administer remedies which depend for their efficacy on the powers of absorption, so markedly lessened in this disease. Even the utility of saline injections direct into the blood channels has too often been found to be illusory, the temporary rally from a state of collapse being followed by a return of the purging with fatal issue. As Dr. Goodeve points out, in his article in Reynolds's System of Medicine, there have been found "no means of keeping the injected fluid within the vessels."

THE BERLIN PHYSICIANS AND CHOLERA.

The Berlin Clinical Society (Verein für innere Medicin) at the meeting on the 14th inst. discussed the subject of cholera. Dr. S. Gutmann opened the debate, and recommended the formation of a committee to collect and report upon the relative value of various therapeutic measures, and to consider what influence the discovery of the cholera

Digitized by Google

bacillus should have in the adoption of prophylactic and curative methods. An animated discussion followed, and a committee was nominated consisting of Drs. Leyden, Fräntzel, Klaatsch, Reiss, Goltdammer, Lehnert, Baer, Wernich, P. and S. Guttmann, and Guttstadt. Dr. P. Guttmann stated that accommodation for 500 cholera patients could be provided in the city hospital at Moabit. At the commencement of the sitting, Dr. Kronecker exhibited a newly devised apparatus for saline transfusion.

CHOLERA REMEDIES.

Not a day passes without the publication of suggestions for the treatment and cure of cholera; and it is remarkable with what a large measure of faith and credulity such measures are promulgated. It is not possible for us to print all the recommendations we have received, or to notice all those that are being advanced in other quarters. Amongst them may be cited the advocacy by M. Vigouroux of the employment of static electricity (*Progrès Médical*), on the ground of the production of ozone; the revival of calomel by Dr. Dornblüth of Rostock (*Deutsch. Med. Woch.*, July 17th); and of spinal ice-bags by Dr. Chapman. In the presence of so much conflicting advice the recommendations of the London College of Physicians will be looked for with interest, as well as with reliance that the treatment of the disease will be authoritatively laid down upon rational and satisfactory principles.

PRECAUTIONS IN EDINBURGH AGAINST CHOLERA.

On the 22nd instant, at a meeting of the Public Health Committee of the Edinburgh Town Council, it was ordered that all the present precautions against cholera, such as removing nuisances, washing out closes, cleansing stairs, and closing insanitary houses, should be continued. At this particular juncture it was pointed out specially that all cisterns for domestic use should be cleansed, and that in the process of cleansing soft brushes should be employed, lest the skin which forms on lead should be displaced, and thus give rise to the action of water on lead and its untoward effects. We have no doubt that under the skilful direction of Dr. Littlejohn, the medical officer of health for the city of Edinburgh, the above and many other points will be carefully attended to as a safeguard against the inroad of cholera. We would beg to offer the suggestion that the lodging and boarding houses in Edinburgh would be the better for an inspection into their sanitary arrangements. The main danger of the importation of cholera is probably from the direction of Leith by means of the shipping, and it is advisable that sanitary inspection of the vessels should be made, as well as cleanliness maintained, in that port.

CHOLERA AND THE BRINDISI ROUTE.

Owing to the prevalence of cholera on the Continent, the Brindisi passenger route to and from India has been closed, and we learn that this is causing no small amount of inconvenience, trouble, and annoyance to Indian officers returning home or going out to India, and among them there are not a few members of our profession. For them, every day in a short three months' privilege leave is a matter of considerable consequence. It is a pity that the Italian Government cannot be brought to see the futility of quarantine measures, at least in the absurd form in which they are carried out.

CHOLERA ON BOARD A LIVERPOOL BOUND SHIP; PRECAUTIONS AGAINST ITS SPREAD.

Our Liverpool correspondent writes:—"The steamer *St. Dunstan* arrived in the Mersey from Bombay on Thursday, the 17th inst., having called *en route* at Marseilles and remained there for some days. Previous to her arrival in Liverpool she put into Penarth Roads for orders, and reported that there had been sickness on board. In consequence of this information having been duly reported to the health authorities, the vessel was boarded shortly after her arrival by Dr. J. Stopford Taylor, the medical officer of health for the city and port. He found all on board in a very weak condition, two deaths having occurred on the passage from Marseilles. The first was that of John Cummings, fireman, who was taken ill on the 10th, the day after leaving Marseilles, with violent purging and cramp in the stomach. In spite of every attention and the best skill the master could give him he died the following afternoon, having been ill just twenty-one hours. On the 14th, one of the seamen, named Sulham, was taken ill with similar symptoms and died the following day. All on board suffered from choleraic diarrhœa, and at Dr. Taylor's visit were in a highly nervous state, as well as in a condition of great weakness and prostration. It transpired that the vessel was put into a dock into which a portion of the sewage of Marseilles was discharged, and the men noticed particularly at night a strong and offensive effluvium. On the sickness first occurring the captain most wisely decided to throw overboard all the stores and water obtained at Marseilles, and, humanly speaking, it is probable that this promptness prevented the disease from spreading further. Captain Brown, the port sanitary officer, remained on board on Thursday night, and on Friday she was again visited by Dr. Taylor and Dr. Hope, the assistant medical officer of health, who remained all that night. Seven of the crew who remained still unwell, and whose presence tended to alarm the rest of the crew, were removed to the port sanitary hospital (near Bromborough Pool, on the Cheshire side), by Dr. Taylor's advice. The *St. Dunstan* has been thoroughly disinfected, the water in the ballast tanks and bilge water being also disinfected before being pumped out. The seamen's beds have been destroyed and their clothing disinfected before their landing. The result has been that up to the afternoon of Wednesday last no fresh case has occurred, and the crew are quite well. In short, the measures adopted are models of what should be done if we wish to prevent any importation of cholera. Another steamer, the *Van Wraate*, has arrived in the Mersey, having called at Marseilles, but as no communication took place at the latter place, and none of the passengers or crew were infected, the vessel was allowed to enter dock.

REMOVAL OF THE SICK AND INJURED.

ON July 21st, Mr. J. FURLEY read a paper at the Health Exhibition on the Carriage and Removal of the Sick and Injured, of which the following is an abstract:—Until within the last ten or twelve years, the word "ambulance" was almost unknown in this country except in connexion with the Army Medical Service; but in 1870–71, through the efforts of the National Aid Society, more familiarly known as the Red Cross Society, it was so generally adopted in our language that it is now as much misapplied as formerly it was little used. People who are accustomed to think of invalid carriages, hand-litters, and stretchers as "ambulances," would be rather astonished to learn the War Office definition of an ambulance and all that it comprises in men, horses, carriages, medical and surgical stores, and camp furniture. In general hospital work Great Britain is on a level with, and in many respects in advance of, any other country in the world, but whilst much care and attention have been bestowed on the internal economy and hygiene of hospitals, comparatively little thought has been given to the manner in which sufferers are conveyed to them. What the National Aid Society accomplished in 1870–71 belongs to history. England was slow in following the example which had been set by other States, but the British Red Cross Society, when occasion called it into existence, gained in a few weeks a position second to that attained by no other country, not excepting the two powerful belligerents who then occupied the arena upon which all eyes were directed. What the St. John Ambulance Association has done during the last six years will fill a no less important page. This differs from the National Aid Society in one particular, that, whilst the latter followed, in its own vigorous and practical manner, examples which were the result of carefully matured thought and experience, the St. John Ambulance Association was a new creation, and no better testimony in its favour can be afforded than the fact that it has already been imitated in every part of the world, with more or less success, and notably by an institution which was originated at Kiel by Professor Esmarch, and is now flourishing in Germany under the title of the "Samariterverein." In the first hours after a great battle, or in the accidents of civil life, there is no more valuable knowledge than that which enables a man to improvise surgical appliances from anything he may find at hand; it is useful to the surgeon, and makes for him ready assistants in others. Except our own, there is not another country in Europe which has not during the last thirty years been more or less directly influenced by the realities of war; for all, if they have not suffered from its actual presence, have without exception

Digitized by Google

left the great blast upon their frontiers. As a consequence of this experience, other nations have more fully realised that saddest part of war, the dead and the wounded scattered over vast battle-fields, the dressing stations where temporary relief is given, the field hospitals, and the long columns of waggons bearing hundreds of maimed men to the base of operations. All this and much more than it is necessary to describe in detail have, in a great measure, familiarised other European nations, and the United States of America, with military ambulance material and its uses, and civilians have vied with soldiers in the endeavour to keep the means of saving life and alleviating the sufferings of the wounded on a level with those means of destruction which military skill and scientific knowledge are ever striving to bring to perfection. The Exhibition held in connexion with the Red Cross Conference at Berlin in 1868, the important Ambulance Department of the International Exhibition at Vienna in 1873, the Hygienic Exhibition at Brussels in 1876, the Red Cross Exhibition at Geneva in 1882, the display at the Health Exhibition at Berlin in 1883, and the frequent meetings which have been held in Paris under the auspices of the Société de Secours aux Blessés Militaires have given great encouragement to this feeling, and much practical advantage has been derived from the trials and comparisons which were made of the means of hospital transport adopted by various nationalities. But in England no similar advantages have been enjoyed, and the number of surgeons and laymen who have taken part in these experiments is very limited. Had the ambulance group of exhibits in the present Exhibition attained that standard which continental critics might have expected, the fact would have been evident that we are beginning to realise our shortcomings, and we might have satisfactorily proved by demonstrations that we are not only taking lessons from the Continent of Europe and the United States of America, but that we are striking out paths of our own towards results which must have a world-wide influence. Ambulance work has a great future before it in England, more particularly as the country generally has not committed itself to any irretrievable steps involving considerable pecuniary sacrifice. Hitherto invalid transport, except at the cost of parishes, for short journeys to the workhouse or the hospital, has been limited to the rich. An attempt, however, should now be made to bring it within the reach of everyone, and to extend to all classes the benefit of change of air and scene when ill-health shall have made such change desirable; or when, as so often happens, a breadwinner is obliged to separate himself from his family because an invalid wife or child cannot be moved to a new home. Just in the same manner as it is mockery to recommend indigent patients when discharged from a hospital a diet of chicken, jelly, and port wine, unless it be provided for them, so it is useless to tell them to obey the doctor's instructions and seek change of air, unless such a possibility is brought within the means of the poorest.

WILLS OF MEDICAL MEN.

The will, with two codicils, of Alexander Tweedie, M.D., M.R.C.P., F.R.S., of Bute Lodge, Twickenham, who died on May 30th last, was proved on the 24th ult. by Mr. Edward Lawes Bevir, Q.C., Mr. Henry Daniel Bishop, and the Rev. Charles Creaghe Collins, the executors, the value of the personal estate amounting to upwards of £181,000. The testator, after making provision for his wife, daughter, and granddaughters, bequeaths £1000 each to the British Medical Benevolent Fund and University College Hospital; £500 each to Charing-cross Hospital, the Royal Hospital for Incurables, Putney, the Great Northern Hospital, Islington, the Scottish Hospital Corporation, the Royal Infirmary, Edinburgh, and the London Fever Hospital, Liverpool-road, Islington; £100 each to the Richmond Hospital, the Artists' Benevolent Fund, London, the Foundling Hospital Benevolent Fund, and the City of London Truss Society; £100 to the Vicar and Churchwardens of East Twickenham towards rebuilding the church, and numerous other legacies. As to the residue of his estate and effects, he leaves one-fourth to his daughter, Mrs. Hannah Cassel Collins, one-fourth each to his grandsons, Alexander Leslie Tweedie and George Alexander Tweedie, and one-fourth between his granddaughters Adelaide Leslie Tweedie and Ann Scott Tweedie.

The will of Frederick Appleton Sawtelle, M.D., of 129, Western-road, Brighton, who died on May 2nd last, at sea, was proved on the 27th ult. by Mrs. Flora Maria Robertson, the sole executrix, the value of the personal estate amounting to over £3600. The testator leaves his interest in a New York Life Assurance Society, to the amount of £1000, to Miss Emily Constance Wright, and subject thereto all that he dies possessed of to Mrs. Robertson.

The Irish probate, granted at Belfast, of the will and codicil of Cunningham Mulholland, M.D., of 41, Prospect-terrace, Belfast, who died on May 14th last, to Mrs. Letitia McDonald Mulholland, the widow, Cunningham Mulholland, the son, and the Rev. William Lowny Berkeley, the executors, was sealed in London on the 1st inst., the aggregate value of the personal estate in England and Ireland exceeding £2900. The testator leaves £100, his household furniture and effects, and an annuity of £60 to his wife; and life annuities to each of his children except his eldest son. All his real estate and the residue of the personalty he gives to his eldest son, the said Cunningham Mulholland.

The will of William Job Collins, M.D., of 1, Albert-terrace, Regent's-park, who died on May 10th last, was proved on the 19th ult. by Mr. W. J. Collins, the son, the sole executor, the value of the personal estate exceeding £1400. The testator leaves £500 to his son Edward Treacher Collins, and the residue of his property equally between him and his daughters, Mrs. Minnie Moor and Mrs. Anne Sarah Chipp.

The will of Henry Francis Williams, M.D., Deputy-Surgeon-General (retired) of Her Majesty's Indian Medical Service, late of Catherine Villa, Auckland-road, Southsea, who died on April 27th last, was proved on the 27th ult. by Mrs. Margaret Anne Williams, the widow and sole executrix, to whom he leaves everything of which he shall die possessed absolutely. The value of the personal estate amounts to over £1200.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. William King, of 19, Ovington-gardens, who directs his executors to transfer to the treasurer or the trustees for the time being of St. George's Hospital, Hyde-park-corner, £100,000 Three per cent. Consolidated Bank Annuities for the purpose of endowing or of augmenting the endowment of such hospital, on condition that a ward in the said hospital shall for ever hereafter be called the "William King Ward."—Mr. James Carthew Quick, of 82, Marine-parade, Brighton, £1000 each to the London Hospital, Whitechapel, and the Sussex County Hospital, Brighton.—Mr. John Antoine Bradshaw, of 2, Alfred-terrace, Upper Holloway, the value of whose personal estate amounts to over £28,000, after giving therout several legacies, divides the residue equally between twenty-two charities, among which are the East London Hospital for Children, the Royal Free Hospital, Gray's-inn-road, St. Bartholomew's Hospital, King's College Hospital, University College Hospital, the Middlesex Hospital, the British Home for Incurables, and the Royal Hospital for Incurables.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria at Tichmarsh, by Mr. W. H. POWER.[1]—Tichmarsh is a village of some 900 inhabitants in the Thrapston rural sanitary district in Northamptonshire, and diphtheria, which made its appearance there in the spring of last year, lingered on throughout the summer, then underwent a sudden extension in October and November, declining again in the early part of this year. In all, nineteen cases terminated fatally. As in so many instances, this disease was preceded by sore-throats and colds of a sort that did not get recorded, and since cases occurring in Poor-law practice were absolutely withheld from the medical officer of health,

[1] To be purchased of Knight and Co., 90, Fleet-street; Shaw and Sons, Fetter-lane; Haddon, Best, and Co., Fetter-lane; and P. S. King and Son, King-street, Westminster.

Digitized by Google

but little information tending to explain the origin and sequence of the disease was forthcoming. When the disease was first known of, it seemed to be related to school attendance, but since the privies at the school alone appeared to present defects, attention was in the main centred on the village water-supply, and several wells having been subjected to analysis they were closed. When school work ceased during harvest time, the school was left closed for a considerable period, until all cases of distinct diphtheria had ceased; but attention being given exclusively to typical cases, and not to the minor attacks of sore-throat, the outbreak underwent a rapid increase when school operations were recommenced towards the end of September. No history of importation could be ascertained, and although locally the disease was regarded as related to certain cases of foot-and-mouth disease, yet this latter disease was at the time prevalent over a wide area, whereas the diphtheria was strictly limited to Tichmarsh. School attendance must be regarded as having influenced the spread of the affection, but it required something more than this; and as Mr. Power points out, it was not until the well-known season of normal extra activity of diphtheria—viz., October to November, that the disease appeared able to take full advantage of the conditions of school attendance for spreading itself amongst the village children. The main sanitary defects which have been revealed in Tichmarsh as the result of Mr. Power's inquiry are the total absence of any means of sewerage, and with this resort to wells, either sunk in the superficial soil above the oolite rock, or through it into a bed of clay below. Pollution of these wells is chiefly due to the circumstance that the water in the superficial rock is largely supplemented by the soakage of filth, and it is this condition which calls for special action on the part of the sanitary authority. Care should also be taken during the forthcoming autumn to get the earliest information as to any cases of sore-throat, so that the families in which they occur may be at once excluded from school attendance.

Diphtheria at Eversholt, by Dr. PARSONS.[1]—This is a village of 768 inhabitants in the Woburn Union, Bedfordshire, and it consists of some fourteen distinct hamlets or ends, where the public health is well looked after by Dr. Prior, the medical officer of health. The place has many natural and sanitary advantages, but it has, notwithstanding, since July, 1883, been the scene of a considerable and persistent prevalence of diphtheria, which up to the date when the inquiry was made had caused forty-one attacks and thirteen deaths. In considering the cause of the disease the influence of sewers and water-supply could be excluded, and since the milk-supply available was from several independent sources, and since some of those attacked never used milk at all, that vehicle of infection could also be set aside. There is, however, a strong probability that the infection was imported into the district by means of a boy who, living in a house where diphtheria had prevailed and who himself having had what was believed to be scarlet fever, came to stay at Eversholt, where his friends kept a public-house. Frequenters of this inn are stated to have been the first persons attacked. The disease was also limited to the parish of Eversholt, and this fact is strongly in favour of the theory that the cause of its propagation was solely personal intercourse; a parish being not a physical but a social division. Dr. Parsons traces the method of personal intercommunication, and, dealing at some length with the question of school influence, he finds from the facts which came under his observation that diphtheria must, like measles and whooping-cough, be regarded as infectious before the characteristic symptoms of the affection have become developed; and the persistence of the disease, in spite of the active measures taken by the sanitary authority for its prevention, is regarded as having been essentially due to the succession of mild and unrecognised cases. The persistence with which the infection of diphtheria is apt to attach itself to certain places is illustrated by the following instance:—In a house in one of the hamlets known as Church End several members of a family had been attacked with diphtheria in December, but in the course of January all had either recovered or died. The house was subsequently fumigated with burning sulphur, the wall paper stripped off, and the walls limewashed. The floors, which were old and irregular, were washed with carbolic soap. Infected articles of clothing were either burnt, washed, or fumigated. On February 8th a daughter came home from service with a bad finger, and on February 13th she was taken ill with diphtheria. She had slept in a room which had been occupied by the sick, but which had been purified as above described. She had noticed, however, a bad smell in the neighbourhood of the fireplace, where certain articles soiled by the sick had been burnt. Also a piece of list nailed around the door-frame, to exclude draught had been allowed to remain. The list, which, from its position, would intercept particles floating in the air entering or leaving the room by the chink of the door, was found full of dust.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6018 births and 4031 deaths were registered during the week ending the 19th inst. The annual death-rate in these towns, which had been equal to 19·5 and 22·2 per 1000 in the two preceding weeks, further rose last week to 24·0, and exceeded the rate recorded in any previous week of this year. This increase was entirely due to the fatal incidence of infantile summer diarrhœa. During the first three weeks of the current quarter the death-rate in these towns averaged 21·9 per 1000, against 18·9 and 20·6 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 14·0 in Bristol, 15·2 in Huddersfield, 15·7 in Portsmouth, and 16·4 in Hull. The rates in the other towns ranged upwards to 27·3 in Leeds, 27·8 in Preston, 29·2 in Nottingham, and 34·6 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 572 and 876 in the two preceding weeks, further rose to 1257 last week; these included 838 from diarrhœa, 129 from whooping-cough, 117 from measles, 83 from scarlet fever, 36 from "fever" (principally enteric), 29 from diphtheria, and 25 from small-pox. No death from any of these diseases was registered last week in Wolverhampton, while they caused the highest death-rates in Leeds, Nottingham, London, Preston, and Leicester. The greatest mortality from diarrhœa, mainly infantile, was recorded last week in Leeds, Nottingham, Preston, and Leicester; from whooping-cough in Sunderland and Liverpool; from measles in Blackburn and Liverpool; from scarlet fever in Cardiff and Brighton; and from "fever" in Plymouth. The 29 deaths from diphtheria in the twenty-eight towns included 19 in London, 5 in Nottingham, and 2 in Leeds. Small-pox caused 30 deaths in Greater London, 1 in Sheffield, and 1 in Liverpool. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1368 and 1241 on the two preceding Saturdays, had further declined to 1152 at the end of last week; the number of new cases admitted to these hospitals also declined to 141 last week, from 266 and 179 in the two preceding weeks. The Highgate Small-pox Hospital contained 68 patients on Saturday last, against numbers declining from 90 to 79 on the four preceding Saturdays; only 8 new cases were admitted during last week, against 20 and 18 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 231 and 206 in the two preceding weeks, further declined to 177 last week, and were 81 below the corrected average. The causes of 75, or only 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Portsmouth, Hull, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Wolverhampton, Birkenhead, and Oldham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·8 and 24·0 per 1000 in the two preceding weeks, rose to 22·8 in the week ending the 19th inst., and was 1·4 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·9 and 17·5 in Aberdeen and Edinburgh to 27·3 in Leith and 27·7 in Paisley. The 549 deaths in the eight towns included 57 which were referred to diarrhœal diseases, 26 to whooping-cough, 11 to "fever," 11 to diphtheria, 7 to scarlet fever, 4 to measles, and not one to small-pox; in all 116 deaths

Digitized by Google

resulted from these principal zymotic diseases, against 78 and 87 in the two preceding weeks. These 116 deaths were equal to an annual rate of 4·8 per 1000, which was 2·7 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœal diseases, which had been 13 and 32 in the two previous weeks, further rose to 57 last week, and were 30 above the number returned in the corresponding week of last year; they included 34 in Glasgow, 7 in Edinburgh, 5 in Dundee, and 5 in Paisley. The rate of mortality from diarrhœa in the Scotch towns last week was, however, very considerably below that recorded in the large English towns. The 26 fatal cases of whooping-cough in the Scotch towns showed an increase of 3 upon the number in the previous week, and included 13 in Glasgow, 5 in Edinburgh, and 3 in Dundee. Ten of the 11 deaths from "fever," and 6 of the 7 from scarlet fever, were recorded in Glasgow, the mortality from "fever" in this city showing a marked increase compared with the returns for recent weeks. The 11 deaths referred to diphtheria in the eight towns showed an increase upon recent weekly numbers, and included 4 in Glasgow, 3 in Edinburgh, and 2 in Dundee. The 4 fatal cases of measles, of which 2 occurred in Glasgow and 2 in Dundee, showed, however, a further decline from the numbers in recent weeks. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 83 and 54 in the two previous weeks, were 66 last week, and within 3 of the number returned in the corresponding week of last year. The causes of 89, or more than 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 21·0 and 22·3 per 1000 in the two preceding weeks, was 21·9 in the week ending the 19th inst. During the first three weeks of the current quarter the death-rate in the city averaged 21·7 per 1000, the rate during the same period being equal to 23·2 in London and only 17·4 in Edinburgh. The 147 deaths in Dublin last week showed a decline of 3 upon the number in the previous week, but included 24 which were referred to the principal zymotic diseases, against 18 and 13 in the two preceding weeks; 7 resulted from "fever" (typhus, enteric, or simple), 6 from whooping-cough, 6 from diarrhœa, 5 from scarlet fever, and not one either from small-pox, measles, or diphtheria. These 24 deaths were equal to an annual rate of 3·6 per 1000, the rate from the same diseases being 9·9 in London and 3·2 in Edinburgh. The deaths referred to "fever" in Dublin, which had been 2 and 5 in the two previous weeks, further rose to 7 last week. The fatal cases of scarlet fever and whooping-cough each also showed an increase of 2 upon the respective numbers in the previous week. The deaths attributed to diarrhœa, which had been but 3 in the previous fortnight, rose to 6 last week. Only 1 inquest case and 2 deaths from violence were registered; the 60 deaths recorded in public institutions showing, however, an increase. The deaths of infants showed a decline from the number in the previous week, while those of elderly persons remained stationary. The causes of 14, or nearly 16 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

CHOLERA.

To the Editor of THE LANCET.

SIR,—In sending you the brief extracts from my official reports on the Cholera Epidemic of 1853, and which were republished in THE LANCET of July 5th, I purposely refrained from comment, with the belief that any remarks in explanation were unnecessary. From what has appeared, however, I am not sure that this is the case. From a perusal of those extracts it is evident that the so-called vibriones are none other than the cholera bacilli of Koch, the discovery of which is all but universally attributed to that distinguished observer.

In THE LANCET of July 12th, under the heading "Dr. Tommasi Crudeli on 'Cholera,'" the following statement occurs:—"Dr. Filippo Pacini of Florence, who died just a year ago (see THE LANCET, July 21st, 1883), in 1854 was the first to recognise the cause of cholera in a microscopic organism which Dr. Tommasi-Crudeli in 1882 classified amongst the germs which multiply by division, &c." Whether I or Pacini was the first to observe the bacillus in question I have at present no means of determining. I would remark, however, that while I recognised the importance of this discovery I did not go the length of describing it as the cause of cholera.

But my object in addressing this communication to you is not merely to bring forward my own claims in the matter, but to urge my views of what I think should be one of the chief objects of the rational treatment of this disease. As I pointed out in the quotations from my report, the bacilli abound even in the secretions of the small intestines; that these sometimes are more or less decomposed and offensive, and that they are alkaline; that, in fact, in the intestines all the conditions exist which are highly favourable, or rather, I should say, are necessary, to the development and multiplication of those and other allied species of bacilli. One of those conditions is the presence of nitrogenous matter, and another the alkalinity of the liquid. I had elsewhere previously shown that while many fungi will not grow in alkaline fluids, bacilli, formerly known in most cases as vibriones, will not grow in decidedly acid liquids.

In these facts it seems to me that we are furnished with rational principles of treatment. One of these is to lessen, and if possible to abolish, the alkalinity of the rice-water-like secretions of the intestines, while another is to put a stop to their putrefactive changes. For these purposes a rigidly acid treatment should be carried out. The patient should drink water which has been boiled and strongly acidulated with sulphuric acid, as much acid being taken as can be borne, the reaction of the dejections being carefully watched. Ten- and even twenty-minim doses of the dilute acid I believe to be worthless, however frequently administered. This acid treatment may be combined with the employment of antiseptics, as creasote or carbolic acid, and perhaps better still with thymol, since it is a nervine stimulant, and not a depressant like carbolic acid. The acid and the disinfectant might be in part given by the rectum. The secretions of the alimentary canal being rendered acid, there would, I anticipate, be little to apprehend from the cholera bacillus; its growth would be greatly hindered, if not stopped, and with this arrest of its development the poison would cease to be generated with the formation of which it is credited.

I see by your report from Paris that the treatment of cholera at Toulon consists mainly of the hypodermic injections of ether in the stage of prostration, of atropine to relieve cramps and spasms, and the inhalation of oxygen for threatened coma. This treatment deals simply with certain prominent symptoms, and is merely palliative. Surely the time has now arrived for the formulation of some sound plan or system of treatment, not directed against isolated symptoms mainly, but against the general conditions of the disease, the state of the alimentary secretions and the presence of the cholera bacillus.

I remain, Sir, your obedient servant,
ARTHUR HILL HASSALL, M.D. Lond.

San Remo, July 16th, 1884.

To the Editor of THE LANCET.

SIR,—Allow me to controvert the idea that fresh fruit is injurious at this season, or has any but the most indirect relation to the prevalence of diarrhœa.

A hot summer mostly gives us good and cheap fruit. The severity of our summer diarrhœa is in proportion to the heat of the season, but it is those who seldom or never eat fruit who die from diarrhœa. For every twelve deaths from this cause ten are of infants under two years of age. It is a remnant of the crudest hygiene to prohibit fruit at all in hot seasons and climates. It is a still worse error to make exception to the character of the soil on which fruit is grown. Last week I stated in your columns that crystals of oxalate of lime would not pass from vegetable food into the absorbents and through the capillaries of the human body. I now have to protest against the possibility that any of the microscopic algæ or their spores can be absorbed by growing vegetables, increase in their tissue, or in any way penetrate into fresh fruit. Yet not only has M. Paul Bert, who is generally above superstitious influences, lent support to this theory, but Professor Nothnagel and

Digitized by Google

Dr. Hoffmann of Vienna are said, in a *Times* telegram of July 21st, to declare that vegetables grown on an unwholesome soil are propagators of cholera. This statement is, up to the present time, entirely unsupported by any facts made known or ever submitted to scientific criticism. Are we again to return to the old views of the connexion between diarrhœa and the plum season, and be asked to believe that this high-growing drupe should, in ripening, attract bacilli to enter the roots of the tree and ascend its branches? If so, let us also be careful of this year's vintage from the south of France, and, though it may rival 1874 in quality, leave its enjoyment to those who a few years hence will not fear lest a cholera bacillus should have entered the grape. The only caution needed for fruit, as for other ingesta, in choleraic times, is to avoid excess, and to see that all is sound, clean, and fresh.—I am, Sir, yours truly,

WILLIAM SQUIRE, M.D., F.R.C.P.

Orchard-street, Portman-square, W., July 23rd, 1884.

To the Editor of THE LANCET.

SIR,—At this time, when our sanitary authorities will naturally wish to avail themselves of the experience of recent outbreaks of cholera, I take the liberty to call attention to the excellent volume devoted to the epidemic of 1873 in the United States of America, and issued from the Government Printing-office, Washington, in 1875. The full title-page of the book is as follows:—

"War Department, Surgeon-General's Office.

"*Cholera Epidemic of 1873 in the United States.*

"Reports prepared under the direction of the Surgeon-General of the Army:—(*a*) History of the Cholera Epidemic of 1873 in the United States, by Ely M'Clellan, M.D., Assistant-Surgeon, U.S.A.; (*b*) History of the Travels of Asiatic Cholera, by John C. Peters, M.D., of New York City, and Ely M'Clellan, M.D., Assistant-Surgeon, U.S.A. (*c*) Bibliography of Cholera, by John S. Billings, M.D., Assistant Surgeon, U.S.A."

This book, I understand, was generously distributed to sanitary authorities in this country, and even to individuals on special application. It is rich in facts, warnings, and lessons, which cannot fail to be appreciated in the present position of affairs. I am anxious that, among the many excellent works on cholera, the valuable gift of our American brethren should not be overlooked.

I remain, Sir, your obedient servant,

JAMES W. ALLAN.

City of Glasgow Fever Hospital, Belvidere, July, 1884.

"THE PHYSIOLOGY OF THE FEET."

To the Editor of THE LANCET.

SIR,—Mr. Allen's letter in THE LANCET of July 5th, which I am sorry not to have seen in time for a reply in your next issue, refers to a point in my paper already brought forcibly to my notice. To my opinion I adhere. Mr. Allen imputes to me the supposition that in walking the toes do first touch the ground. I stated that they should do so. I do not think that this is a "common error"; I find that everyone I ask says at once that the heels must touch the ground first. I am, however, glad to hear that the contrary is taught by "some very good physiologiste." While granting that, as a rule, the ground is touched first by the heels in walking with boots, yet I have found that in walking barefooted the toes first reach it. This is certainly so in my own case, and I do not think that, if seen so doing, I should "be supposed to be practising a burlesque step for the stage." But even if it did so seem, that would not prove the form of step to be wrong from a physiological point of view, for it will, doubtless, be admitted that a question of physiology can be settled only by reference to nature, without regard to conventional notions of walking, good or bad, as done now, after many generations who have habitually worn boots more or less interfering with perfect exercise of the functions of the feet. The use of any kind of foot-clothing cannot be presupposed. The human foot, even in savage life, never attains the hardness of sole necessary to make the character of the ground trodden on a matter of indifference in anything like the same degree as in animals provided with hoofs; yet man, in a state of nature, has to tread where his feet are liable to injury, as on broken sticks hidden by verdure or on rocky ground, perhaps in darkness.

It must then, I think, be conceded that, under the conditions given, it is desirable that the part of the foot which first touches the ground should be the part best calculated to estimate the character of the surface to be trodden on; and, further, that the part which last reaches it, as the weight of the body falls fully on the single foot, should be the part least liable to sustain injury, and most easily withdrawn from the gound if it meet, at that point, with any projection of an injurious character.

Now, if the toes, spoken of in the paper as the organs of feeling, and the anterior part of the foot, more sensitive than the heel, first touch the ground, the character of the surface is better estimated, and if the heel as it falls does happen to come on a sharp point, it is easily and momentarily raised, and, the tiptoe position being attained, injury to the heel is avoided. On the other hand, if the heel first touch the ground, not only does the want of sensibility prevent so accurate an estimate of the character of the surface, but worst of all, if, as the body falls forward to be borne on the single foot, the more sensitive part in front should happen to come on a sharp point, there is no recovery. To spring back into a position resting on one heel only is well-nigh impossible. As an exaggerated illustration of my meaning, let anyone try to walk with closed eyes and bare feet across a room where tin tacks have been purposely strewed. I can do it easily walking in the former manner, and bring the heel to the floor in each step. I would rather not try in the latter mode. Of course the movements extremely marked in this experiment would be scarcely perceptible under ordinary conditions. I suggest, however, that in principle they should be identical.

Mr. Allen says that "when the foot is put forward the heel is the part nearest the ground." If the foot in swinging forwards attain fully, as I think it should do, that which I have called "the position of rest," and defined as that of least tension and least pressure, least tension of the ligaments on the bones forming the joints, and least pressure of the bones on each other, or the mean between the extremes of motion, then, to attain this, the foot falls into an extended position with regard to the leg, thus bringing the toes nearest to the ground and ready to feel it. This position, too, allows of the widest range of lateral movement, useful at times, selecting the exact spot to be trodden on. The toes are kept free of the surface by bending the knee, in effect also resting that joint, previously strained by straightening.

On these grounds, as well as the avoidance of concussion, friction, or slipping, I have no doubt that, in walking, the toes should first touch the ground.

I am, Sir, yours faithfully,

Gloucester, July 14th, 1884. T. S. ELLIS.

MANCHESTER.

(From our own Correspondent.)

THE RECENT RAILWAY ACCIDENT.

THE public journals will have informed your readers of the terrible railway accident which occurred on the Manchester, Sheffield, and Lincolnshire Railway last week near Penistone. On receipt of information of the catastrophe at London-road Station surgical assistance was sought at the Royal Infirmary, and some of the resident staff were despatched by train to the scene of the accident. More than twenty were killed on the spot, whilst twenty-three of the more seriously injured were brought on to the Manchester Infirmary, and for a short time the resources of the hospital were taxed in providing immediate assistance and attention to the sufferers. Two died a few hours after admission; one, a young lady, had amputation of the thigh performed, but succumbed shortly after the operation. Three of the cases still remain in a critical condition, two of them being cerebral injuries; the patients, one a man the other a woman, remained unconscious until Monday last. They are now slowly regaining consciousness. The third is a fracture of leg with compound dislocation of the ankle, and will require amputation as soon as the condition of the patient will permit. Amongst the injured lying at the infirmary is a man of some local celebrity named Rawlings, known as the "Reddish Doctor," and famed as a curer of cancers.

LAW AND MEDICINE.

On Monday last, at the assizes now being held here, Mr. Justice Day made some remarks upon the evidence given by medical witnesses, which, to say the least, were uncalled for if not unjust, for, as one of the local papers put it, "it is highly undesirable that so much contempt should be expressed for scientific evidence without a stronger reason than in this case is apparent." In summing up to the jury, at the conclusion of a case in which a man was upon his trial for the murder of his father, the judge is reported to have said:—"You must sacrifice your own views and your common sense. You are bound by what the doctors say. No one but a doctor knows or could have any doubt about it; but juries must be guided by their evidence, and you must acquit the prisoner. Although it is proved to your satisfaction that from the time this man was struck he gradually lingered and then died, if the doctors say the blow had nothing to do with the death you must acquit the prisoner. You cannot convict on this evidence. I can very well understand, even where a man's life is at stake, the reluctance you feel at stultifying yourself by giving such a verdict. After what you have heard from the counsel for the prosecution and this doctor, you would not be justified in finding this man guilty of murder, although I am sure, as men of common sense, you are satisfied of it. Nobody can doubt it, except these doctors." The main facts of the case and evidence which led to the above remarks were as follows. On May 17th, the prisoner Joseph Saxon, aged twenty-five, struck his father, the deceased, who at the time was in his usual health, a violent blow upon the head with a hammer, with the avowed intention of killing him. The wound was at once attended to at the Ardwick and Ancoats Dispensary, and two of the surgeons there, Mr. Scott and Mr. Webster, could detect no fracture, and considered the wound not of a serious nature. The man in a day or two was again able to work, and the son was sentenced to two months' imprisonment for a common assault. On May 23rd the deceased man felt worse, and went to the surgery of Dr. C. Smith, who, with his son, examined the wound, and found it still unhealed, but there were new symptoms pointing to some cerebral lesion. The man rapidly became worse, hemiplegia and coma coming on, and he died on the 26th, nine days after the receipt of the original injury. At the necropsy a slight depression of the inner table of the skull was found beneath the seat of the wound, but little or no hæmorrhage or other injury to the brain substance beneath; but in one of the ventricles a large quantity of blood was found, with a clot the size of a hen's egg. To this hæmorrhage there was no doubt death was due, but as counsel for the defence brought out in cross-examination, it could not with certainty be said whether this hæmorrhage had any direct connexion with the blow received or not. The clinical symptoms appeared rather in favour of the negative view, and the defence set up was that death was caused by an apoplectic seizure coming on six days after the blow was given, and due to violent excitement and passion, which it was shown the man gave way to just before the symptoms of apoplexy came on. From these facts most of your readers will agree that there was room for considerable and justifiable doubt whether the hæmorrhage, which undoubtedly caused death, was directly connected with the blow inflicted on the 17th, and that no medical man could have sent a fellow creature to the gallows without more convincing proof of the cause of the apoplexy than was forthcoming.

Dr. Roscoe, Professor of Chemistry in Owens College, has recently had the honour of knighthood conferred upon him in recognition of his services in connexion with the Technical Education Commission, though, doubtless, his European reputation as a chemist had also something to do this mark of distinction being offered to him.

The first public intimation of the above was made by Mr. Mundella, M.P., during his late visit here for the purpose of opening a new Board School for higher grade scholars, which he declared to be one of the most complete institutions of its kind in the kingdom; and a new museum lately built by the corporation in Queen's Park, which lies to the north-west of the city, and is a most admirably adapted building for the purpose for which it is intended. The museum is at present largely filled with objects and art treasures lent by the Government from South Kensington. Its situation, near a densely populated part of the city, reflects great credit upon the corporation, who certainly are in many ways attempting to provide for the masses of the people healthy and instructive recreation.

Allusion was recently made in these columns to the fact that the Medical Department of Owens College was likely soon to lose the valuable services of Dr. Gamgee. Although he will no longer be dean of the school, arrangements have been made by which for the present he will devote some of his time to the work of the College, retaining the Professorship of Physiology, whilst an additional assistant in the physiological laboratory will be appointed to aid in the practical work of the students there. It is rumoured that Dr. M. Watson, Professor of Anatomy, will succeed Dr. Gamgee as dean.

On Degree Day of the Victoria University there was a large attendance of visitors, including many ladies and old associates of the college. Degrees in Arts and in Science were conferred by the Vice-Chancellor, but none yet in Medicine, though it is expected that at the next ceremonial there will be several medical graduates in the pass list.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

A MEETING of the Fellows was held last Monday for the purpose of electing a vice-president in the vacancy caused by the resignation of Mr. Corley, who is a candidate for the Professorship of Surgery, and was obliged to resign office in order to qualify for the appointment. There were two candidates—viz., Dr. Cameron, a professor in the College School and superintendent medical officer of health for Dublin, and Mr. Ormsby, surgeon to the Meath Hospital. The latter opposed Dr. Cameron because he was of opinion that a surgical corporation should be represented by a practising surgeon, and, as a general rule, no doubt such should be the case. But Dr. Cameron, although he does not practise surgery, yet is a distinguished pathologist, histologist, and analytical chemist, and is the leading authority in Ireland upon sanitary science, and has rendered valuable services to the citizens of Dublin in his capacity as medical officer of health. For these and other grounds the Fellows supported him, and he was returned as vice-president by a very large majority. At the same meeting an election for a member of Council took place. For this there were four candidates, Mr. Austin Meldon being successful by a majority of seven votes. The election to the Professorship of Surgery in the College takes place this week, when Messrs. Corley and Hamilton compete for the vacancy. It is expected to be a very close contest, and that two or three votes may decide the matter. Mr. Edward Hamilton, ex-vice-president, has been elected Professor of Surgery in the medical school of the college.

PRECAUTIONS AGAINST CHOLERA IN DUBLIN.

The superintendent medical officer of health (Dr. Cameron) has had several interviews with the Local Government Board in reference to the necessary measures to be adopted in case the cholera should become epidemic. The Board are prepared to constitute the corporation the sole authority under the 149th clause of the Public Health Act, and under its provisions they will have power to erect hospitals, appoint physicians, and arrange for a house-to-house visitation. The Public Health Committee have held a special meeting, and have recommended the corporation to accept the responsibility. The College of Physicians have reissued a memorandum in reference to the disease, and state that an isolated intercepting hospital containing twenty beds should be prepared within a convenient distance of the river. As regards the difficulty of procuring sites for cholera hospitals, it will be removed by the Cholera Hospitals Bill, which is now before Parliament, should it become law.

AT the recent meeting of the Council of the London Society for the Prevention of Cruelty to Children, it was announced that Lord Shaftesbury had accepted the presidency of the Society.

THE University of Heidelberg is about to celebrate its five hundredth anniversary. The Baden Parliament has voted £8000 to meet the expenses of the occasion.

PARIS.

(From our own Correspondent.)

THE CHOLERA EPIDEMIC.

THE Academy of Medicine, consulted by the Minister of Commerce as to the utility of the measures taken to prevent the spread of cholera, has advised the Government as follows:—(1) Land quarantines intended to prevent the spread of cholera epidemics are impracticable; (2) the means of disinfection now taken at certain railway stations are inefficacious and delusive; (3) the prophylactic measures which are really useful are such as are dictated by general hygiene, particularly those which diminish overcrowding in contaminated places and those which isolate the sick. As regards the progress of the epidemic, no one can pretend to know with certainty more of what happens in Paris than the authorities choose to allow to transpire; but if official statements are true, the sanitary condition of the city is excellent, and up to the present time no cases of Asiatic cholera have occurred in the Paris hospitals. The Directeur de l'Assistance Publique has made a statement to the Municipal Council to this effect, and it now appears that the patients reported as choleraic during the last few days in the papers were simply subjects of diarrhœa and other gastric disturbances. The mortality caused by the epidemic in the South during the last week has somewhat increased in Toulon, whilst at Marseilles it remains stationary. Isolated cases have occurred at various other places; but, with the exception of Arles, there are as yet no new cholera centres. The following figures represent the death-rate of last week:—

July.	Toulon.	Marseilles.	Arles.
15	25	69	0
16	38	53	0
17	38	56	4
18	31	58	6
19	49	65	7
20	42	57	12
21	43	61	8

It is a pity that there is not a little more uniformity of opinion amongst medical men generally as to the proper treatment of the disease; but the fact is, *quot homines tot sententiæ*, and such a state of things is not likely to have a beneficial effect upon the public. Considering the diversity of opinion which exists even on the most elementary points, many of the lower classes will prefer to try the popular remedy, of getting drunk or of drinking lemon juice, &c., rather than apply for help to the orthodox practitioners. It is thought that contaminated drinking water is a means of propagating cholera, and instructions have been issued to the people to boil all that is intended to be so used. No such thing, says M. Colin; such an opinion is entirely erroneous, and can only serve to give false security. It is of the utmost importance, says M. Jules Guérin, to check the premonitory diarrhœa. Of 130,000 patients so treated in London, only 250 had cholera, although 6000 were bordering on the characteristic symptoms of the disease. On the contrary, opines M. Rabuteau, it is better to begin with a purge of sulphocarbolate of sodium, after which astringents, and particularly the tannates of alumina, bismuth, and magnesia, should be used. M. Burq, who has spent his whole life studying the subject, has presented another memoir to the Academy of Sciences to indicate the merits of copper as a prophylactic of cholera. Curiously enough, a telegram recording two deaths in the South, attributes them to the victims having partaken of food prepared in a copper vessel.

THE PATENT MEDICINES STAMP.

The question of the repeal of the Patent Medicines Stamp Act being now before the public, I may remind your readers that an inquiry upon proprietary medicines in France is still pending. Two or three years since, as I reported in THE LANCET at the time, the subject was discussed at the Academy of Medicine, and some of the most eminent pharmacists expressed the belief that it would be better, with perhaps some few exceptions, to abolish patent medicines altogether. The different wines of pepsine came in for special obloquy, as many of them were found to contain scarcely a trace of the active principle; a then popular preparation of iron also received its death-blow. Whatever may be the state of things in other places, such a reform would be a great benefit to the pharmaceutical profession at large in France. The numbers of specialities which are prescribed make private prescriptions quite a rare windfall in a Paris pharmacy, and competition is so great that, although patent medicines are generally high priced, and supplied to the retail chemists at 40 per cent. discount, the vendor is obliged to make a large reduction on the marked price to attract custom, and so gets but small profit. By abolishing the traffic altogether, a few large speculators would go to the wall, but the prosperity of the profession as a whole would be greatly increased. As the law now stands, any chemist may devise a speciality without going through any formality or paying any stamp duty. He may of course supply it to the trade, but if he retails it without a prescription he does it at his own risk and peril, the sale being tolerated when the medicine is of an inoffensive character, but rendering him liable to prosecution if this condition is infringed. Legally the chemist has no right to sell without a prescription anything but a few drugs and chemicals. The sale of an emetic or of castor oil on his own account renders him liable to prosecution; and although, as has been stated, no stamp or formality is required for patent medicines, their sale is only tolerated, and could be prevented in any case.

PREPARING FOR CHOLERA IN PARIS.

(From a Correspondent.)

The cholera more than ever engrosses public thought, and in medical circles is the principal, if not the only, subject of discussion. Nor is this solely a matter of conversation. Two notable measures have been adopted. Dr. Dujardin-Beaumetz, Member of the Council of Hygiene and Salubrity for the department of the Seine, is organising throughout Paris a sanitary service. Medical officers of health are now being appointed for every district. Orders are given that any illness of a choleraic nature must be reported at once to the nearest police station. The prefect of police is then communicated with by telegraph, and the medical officer is ordered to superintend personally the disinfection of the house where the case is reported. But the question arises as to what is meant by the term disinfection, and who is to do the work which these newly created medical officers are called upon to superintend. So far either policemen or firemen have been employed; and, on the whole, a distinct preference is shown for the latter. They are brave, active, and accustomed to constant alarms; on the other hand, they are young men, very susceptible to contract diseases, and may possibly infect the barracks in which they live. The term disinfection is also employed in a very vague manner. It generally means a good scouring, and but for the plentiful use of carbolic acid or chloride of lime would be little better than an English "spring cleaning." While, however, Dr. Dujardin-Beaumetz is organising the machinery for the disinfection of houses, M. Pasteur is conducting a series of experiments for the purpose of ascertaining what may be considered effective disinfection. In conjunction with several other medical men, some civil engineers, and the prefect of police, M. Pasteur has been every morning to the Hôpital Cochin, where experiments were organised in the following manner. M. Pasteur selected from his laboratory the microbes of chicken cholera, of anthrax, lymph of small-pox (both moist and dry), and other similar subjects. These specimens were divided into three equal parts, and placed in three different small rooms at the hospital. In one room common sulphur was burnt; in the second liquid sulphurous acid was injected through the door by M. Pictet; and nothing whatever was done to the third room. After twenty-four hours the microbes were examined, and calves were vaccinated with the small-pox lymph. The result so far goes to show that the sulphurous acid, whether derived from the fumes of burning sulphur or from M. Pictet's syphon bottles containing the liquid form, did not disinfect at all. M. Pasteur showed me some cultures, notably those of splenic fever, which had developed themselves with great activity in spite of twenty-four hours' sojourn in the midst of sulphurous acid gas. At the same time, I must state that the experiments were in no wise conclusive. The amount of sulphur employed was small—750 grammes to 80 cubic metres,—and now the experiments are being repeated with a far stronger proportion of sulphurous acid; and if the liquid form is employed, there will be no difficulty in attaining the required strength. But this is expensive. At present five francs a litre is the price demanded, though probably this will be reduced to

Digitized by Google

two or three francs. Yet even at this price the disinfection of a room will cost from ten to twenty shillings, according to its size. The Hôpital Bichat and the Hôpital Broussais will be devoted especially to the treatment of cholera cases should the epidemic break out in Paris. The former hospital has only just been completed. It is built, according to the Tollet system, in pavilions that have 120 angles, being of the Gothic arch shape. It is spread over a large extent of waste space in the fortifications to the north of Paris, occupying in all 7700 square metres, but the hospital cost only £40,310, including the price of the land. Each pavilion is thoroughly separated from the neighbouring pavilions, contains thirty beds, giving a surface measurement of 11 metres per bed, and a cubic capacity of 60 metres per inmate. These rare advantages place this hospital first among the model hospitals of France, and the results already obtained in this building are most favourable. The idea of employing the Château de Brévannes, which it is proposed to convert into an asylum for the aged and infirm, as a cholera hospital is not so promising. This magnificent but antiquated building cannot be considered as equal to the modern exigencies of sanitary science, and I trust that no more infirmities than those inherent to old age will be treated in this building. Better far the proposed erection of wooden huts in the fortifications, though the ambulance of the Tollet type (such as may be seen behind the dairies at the Health Exhibition) would be even better suited to this purpose. They take only eight hours to construct, and may therefore be brought anywhere to meet a sudden emergency. As this model has been definitely adopted by the Ministry of War, an epidemic would be a good opportunity of testing the practical worth of the Tollet ambulance. In the meanwhile, the news from the south of France is more and more menacing. The epidemic has fairly invaded Arles. It seems to have begun in several other places, and is slowly travelling north. The proportion of fatal cases has greatly increased, amounting to as many as six in seven at Toulon, while the duration of the attack varies from six to eleven hours. Such was the official information given to me yesterday by Dr. Proust. Under these circumstances it is indeed fortunate that the authorities have displayed some activity, and are anxiously struggling to save Paris from this terrible scourge. The *Journal Officiel* to-day publishes the ministerial circular to the prefects on the subject, ordering the disinfection of all houses where cholera has occurred, but not describing how this disinfection is to be accomplished. The Government is evidently waiting for the conclusion of M. Pasteur's experiments.

Paris, July 22nd, 1884.

EGYPT.

(From a Correspondent.)

THE committee attached to the Egyptian Sanitary Department has now definitely resolved to abandon all idea of land quarantine and sanitary cordon in the event of another visitation of cholera. Most observers will allow that the strenuous efforts of the police in 1883 were a decided failure and had no salutary effect, while the needless disadvantages of the system are well known to most Englishmen. The committee, consisting of four native and two English doctors, has, therefore, unanimously decided upon adopting the conclusions come to at Vienna in 1874 by the International Sanitary Conference: "Considering that land quarantine is impracticable and useless, in consequence of the frequent and always increasing means of communication, and believing that it is fatal to all commerce, the conference rejects quarantine altogether." Although the committee frankly acknowledges that the isolation of the first village attacked is a useless and inhumane measure, it permits the sanitary department, in case of urgent need, such as allaying a panic, to recommend the measure to the Government, only stipulating that it shall cease to be employed directly the disease appears in a second town or village. The committee, of course, recommends many sanitary proceedings, such as the cleansing and scavenging of towns and villages, the evacuation of the first house infected, the substitution of earth trenches for mosque latrines in case of epidemic, the boiling of drinking water, the postponement of all fairs and cattle markets till the month of November, &c. No tents at present belonging to Government service which are not required for the Egyptian army, and means will at once be taken to procure a sufficient number for the provinces, in order to treat the sick of an epidemic, and those natives who may be evacuated from their homes. The resolutions of the sanitary committee have been approved by the Council of Ministers.

Examination of the last week's death returns from the three large towns of Egypt gives the following result:—The average daily death-rate for Cairo is 52, of which cases 23, or 44·2 per cent., are from intestinal diseases, and at least half this number are returned as gastro-enteritis in children. In Alexandria it would appear that 20 deaths occur daily, 5½, or 27·1 per cent., of them being accounted for by diarrhœa, typhoid, and kindred complaints. At Tantah there is an average daily rate of 10, with about 2 cases only of intestinal disease, or 21·4 per cent.

It is interesting at this time to look back to the account of the reappearance of cholera in Lower Egypt in 1866. The first known case in that year was on March 8th, and was traced to a fatal form of diarrhœa which prevailed in the workshops of the Isthmus Canal Company at Chalouf. Three other cases occurred in March and three more in April, all at Alexandria or Suez. In May the usual mortality of Suez was doubled, and "choleriforme" was reported, while in June and July dropping cases continued in the seaport towns. In August "cholerine" probably existed in Tantah and Cairo, and in three days it killed 8 per cent. of a population of 300 at a small village near Zagazig. On September 12th a considerable outbreak of epidemic cholera occurred, and for a short period the cases numbered, it is believed, sixty daily. On November 11th the disease had almost disappeared, and its complete cessation was reported on November 20th, 1866.

Cairo, July 13th.

THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon Robert Owen Hayden has been placed on temporary half-pay on account of ill-health.

ADMIRALTY.—Staff Surgeons William Middleton Power and John Neesom Stone have been promoted to the rank of Fleet Surgeon in her Majesty's Fleet.

The following appointments have been made: Robert W. Soper, to be Surgeon and Agent at Dartmouth; and Patrick T. Dillon, to be Surgeon and Agent at Tarbert.

MILITIA MEDICAL DEPARTMENT.—Surgeon-Major Henry Cooper Rose, 4th Battalion, the Duke of Cambridge's Own, (Middlesex Regiment), resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

RIFLE VOLUNTEERS.—7th Middlesex (London Scottish): Leslie Ogilvie, Gent., M.B., to be Acting Surgeon. James Rowlands Essex, Gent., to be Acting Surgeon.

MEDICAL NOTES IN PARLIAMENT.

The State of the Thames.

IN the House of Commons on Friday, Sir C. Dilke, replying to Sir A. Lusk, expressed his regret that the select committee had thrown out the scheme of the Joint Drainage Board for the Lower Thames Valley, and observed that now there was nothing to prevent sewage in a crude condition from being poured into the river.

Further questions were put on Monday by Sir F. Milner and Mr. Macfarlane as to the state of the river near Greenwich, but nothing new was elicited.

The Indian Medical Service.

Mr. Gibson, in an able speech, brought forward, on Friday, his motion, "That the condition of the Indian Medical Service calls for the early attention of the Government, and this House trusts that measures will soon be taken to lessen the block in promotion and the disappointment at the methods of employment and pay which exist in its ranks."—Sir L. Playfair seconded the motion, which was supported by Mr. Leamy, Dr. Lyons, Mr. Plunkett, Dr. Farquharson, and Mr. Healy.—Mr. J. R. Cross replied that the Government could not accept the resolution, but he would bring the subject before the Indian Government. At

Digitized by Google

the same time he expressed an opinion that the Indian Medical Service was better than the British, and that the reduction of the number of yearly appointments was diminishing the block in promotion. The motion was negatived without a division.

The Cholera.

On Monday, in reply to Mr. Gray, Mr. Trevelyan stated that the Corporation of Dublin would be empowered by the Local Government Board to carry out the 149th Section of the Public Health Act in the event of cholera making its appearance. A floating intercepting hospital was ready in the harbour, and the medical officers were on the alert. The Local Government Board had full information as to the best means of obtaining portable hospitals.

Sir C. Dilke informed Dr. Cameron that the importation of rags from Marseilles and Toulon had been prohibited, and a cargo from the former place, which had been landed near Hull, would be sent back.

Lunacy Accounts.

Mr. Hibbert informed Mr. Corbet that the total annual cost of all English lunatic asylums appeared in the abstracts of the asylum accounts which were forwarded to the Lunacy Commissioners, and which were laid upon the table of the House, but not printed. Four letters had been written without effect to the medical superintendent of the Manchester Royal Lunatic Asylum, asking for his return. There was no separate account of the cost of lunatics in workhouses.

A Volunteer Hospital Corps.

Lord Hartington stated to Sir T. Lawrence that this scheme was not yet sufficiently advanced for the issue of regulations. It would be fully considered when next year's estimates were prepared.

Spurious Butter.

On Tuesday, Mr. Dodson replied to Mr. Dawnay that he was in communication with the Treasury as to separate returns of the imports into this country of injurious butter substitutes.

Vaccination.

Mr. Russell informed Mr. Hopwood that the Local Government Board, believing their opinion against repeated penalties for non-vaccination to be well known, did not think the issue of a fresh circular necessary.

On Thursday, the hon. gentleman expressed approval of a pamphlet on vaccination which had been issued by the National Health Society.

Royal University of Ireland.

Mr. Trevelyan, on Tuesday, stated to Mr. Kenny that the Senate of the Royal University of Ireland granted medical degrees to gentlemen who had passed the Arts course in the Catholic University, or had studied at some other university prior to the establishment of the Royal University.

The Salt Tax in India.

On Thursday, Mr. J. M'Carthy asked the Under Secretary of State for India whether his attention had been drawn to an article in THE LANCET, published two months ago, in which that high medical authority asserted that, "as the diet of the Hindoo is almost entirely farinaceous and vegetable, it is a cruel injustice to impose a tax that renders a physiological necessary a high-priced luxury;" and whether the Government would take into account the opinion of THE LANCET in arranging their future policy with regard to the salt tax in India.—Mr. J. R. Cross said his attention had been called to the article in question. The Government of India were thoroughly alive to the objections that were raised to the imposition of the salt tax, and would bear them in mind in arranging their future policy.

Nenagh Dispensary.

Mr. Trevelyan said, replying to Mr. Leahy, that the Local Government Board had called upon Dr. Calaghan, the medical attendant of the Nenagh Dispensary District of the Nenagh Union, for an explanation of his conduct in respect to alleged neglect of duty. The doctor did not deny that a red ticket might have been left on Friday, the 29th of May last, making it his duty to visit immediately Alice McCormack (the daughter of Mr. John McCormack, carpenter, of Nenagh), a girl who was lying at the time dangerously ill. If such a ticket were left he could find no trace of it. There was neither neglect nor forgetfulness attributable to him, inasmuch as he passed Mr. McCormack's house twice on the day in question, and could have called had he known, without any inconvenience whatever. The doctor had since prescribed for the child, and she was now quite well.

Obituary.

CÆSAR H. HAWKINS, F.R.S.

SERGEANT SURGEON TO THE QUEEN.

To comprise in the space at our command a professional life of seventy years, sixty of which were spent in active work, is difficult. In giving a sketch of the life of Mr. Cæsar Hawkins, who died on Sunday last, we can but refer to the most salient points. He was born on September 19th, 1798, at Bisley, in Gloucestershire, where his father, the Rev. Edward Hawkins, was vicar, who was the youngest son of Sir Cæsar Hawkins, Serjeant Surgeon to George II. and George III., Surgeon to St. George's Hospital from 1735 to 1774, when he was succeeded in that office by his son, Mr. Charles Hawkins, who resigned in 1792, but was re-elected in 1798, and in 1800 was appointed by Charter the first Master of the College of Surgeons of London, he being then Serjeant Surgeon. Mr. Cæsar Hawkins was first at a school in Gloucester, and in 1807 was admitted to Christ's Hospital School, where he remained until 1813, being then of the age when boys who were not going to Oxford or Cambridge were compelled to leave. Two of his brothers—the well-known Provost of Oriel, and Dr. Francis Hawkins, Physician to the Middlesex Hospital—were educated at the Merchant Taylors' School, and both went to St. John's College, Oxford. In 1814 he became an articled pupil to Mr. Sheppard, of Hampton Court, the medical attendant of the Duke of Clarence, afterwards King William IV., when he resided at Bushey-park. Mr. Cæsar Hawkins remained with Mr. Sheppard until 1819, when he became a pupil at St. George's Hospital, and entered to the lectures on Surgery of Mr. Brodie, Assistant-Surgeon, lecturing then in a small theatre in a house opposite the Hunterian School in Great Windmill-street, and to the lectures of Wilson and Charles Bell in that school, to Dr. George Pearson's lectures given at his house in George-street, Hanover-square, to Lectures on Chemistry at the Royal Institution, when Faraday was an assistant in the laboratory. This shows how the centres of education were then scattered.

For many years Mr. Cæsar Hawkins was the prosector in Windmill-street, also assisting Charles Bell and John Shaw in their experiments illustrating the uses of the fifth and seventh nerves. In 1821 he was house-surgeon at the Lock Hospital, in which year he became a member of the College of Surgeons. In 1922 he was house-surgeon to St. George's Hospital, and in 1823 he commenced practice in lodgings in Vere-street, Oxford-street. In 1825 he removed to Half Moon-street, where he took house pupils, and in 1842 to 26, Grosvenor-street, where he died. For some years he dissected and performed experiments for Sir Everard Home. Before leaving St. George's Hospital, he received overtures for teaching anatomy from Charles Bell and John Shaw at the Hunterian School; and also from Herbert Mayo, who had built a small theatre behind his house in Berwick-street. On Mr. Brodie's advice he accepted the latter offer, and there commenced giving anatomical demonstrations. In 1826 the lease of the Hunterian School was bought from Charles Bell by Herbert Mayo and himself, where he continued to teach anatomy until 1830, when he left, with all the St. George's Hospital staff, upon the opening of the school at that hospital, Mr. Mayo leaving in the next year to go to King's College. Mr. Cæsar Hawkins was the last member of the great Hunterian School founded by William Hunter in Great Windmill-street. In 1829 he joined Sir Benjamin Brodie, who was then lecturing on Surgery in the Hunterian School, in delivering part of the course, and continued subsequently to do so at St. George's Hospital, first with Mr. George Babington, and eventually with Mr. Tatum until 1874, after which he occasionally gave Clinical lectures. From 1832 to 1834 he also lectured with Dr. Seymour on Medical Juris-

Digitized by Google

prudence. On leaving Great Windmill-street, the Museum was divided; one half Mr. Mayo took to King's College, the other Mr. Hawkins took to St. George's Hospital, and afterwards presented it to the hospital. On his relinquishing teaching at St. George's Hospital, he was requested to sit for his bust as a testimony of the esteem of his old pupils, which was presented to his wife. In 1828, in the absence of Sir Charles Bell and Mr. Mayo, he was requested by the governors of Middlesex Hospital to undertake their duties as surgeon, which he did for some months. In 1829 he was elected surgeon to St. George's Hospital. This office he held until 1861, when he was elected a consulting surgeon. At the College of Surgeons he held every office: appointed a Fellow by Charter in 1843, a Member of the Council in 1846, Examiner in 1849 (in which year he delivered the Hunterian Oration, in the presence of the late Prince Consort), and President in 1862 and 1861, representative on the Medical General Council in 1865, and in 1871 was elected a trustee of the Hunterian Museum.

From 1845 to 1849 he was an examiner in surgery at the University of London, President of the Royal Medical and Chirurgical Society in 1855 and 1856, of the Pathological Society in 1849 and 1850, and, of the Sydenham Society in 1873 and 1874. He was elected a Fellow of the Royal Society in 1856, appointed Surgeon Extraordinary to the Queen in 1857, and upon the death of Sir Benjamin Brodie in 1862, Sergeant Surgeon, being the fourth of his family holding that office—viz., Sir Cæsar Hawkins, his son Mr. Charles Hawkins, and his brother Mr. Pennell Hawkins, Surgeon to Middlesex Hospital. Mr. Cæsar Hawkins had been consulted by four generations of the present Royal Family. In 1874 he printed for private circulation two volumes containing his communications to scientific societies and medical journals. These were fully noticed by the medical journals, and with great praise. He died, as was stated in a notice of his life in *The Times* of last Monday, as John Hunter did, without receiving any title as a recognition of his merits. A most feeling allusion to his death was made in a sermon in St. George's, Hanover-square, Church, on Sunday. We are permitted to quote the following from a letter written to one of his friends on hearing of his death by one of the most distinguished members of the profession:—"We have lost, I think, the clearest mind in our profession, in which accuracy was least swayed by imagination, or temper, or desire for renown. I have never known one more completely honest or discreet in counsel, or less influenced by self-interest."

Mr. Cæsar Hawkins had been some months before his death more or less confined to his bedroom. Early in last December he met with an accident in going downstairs; he slipped, and though able to recover himself to some extent, he sustained a severe bruise on the left leg, followed by much effusion of blood. Without any subsequent external mischief the effusion became gradually absorbed, but during part of this period there were certain evidences of clot in the larger veins of the same leg, attended by some constitutional disturbance, all of which tended to weaken the system, and cause some anxiety to those in attendance upon him. But by degrees these symptoms subsided, and Mr. Hawkins was sometimes able to sit up, and even on one occasion to leave the house for a few hours. Subsequent to this he became less well, was troubled with cough and loss of appetite, added to which other ailments of advanced life combined to weaken the body and hasten the fatal end. To the last his mind was clear. He rose from his bed early on Sunday morning, became faint and expired in a few minutes.

There are few men who have gone through life more highly respected by all who knew him than the subject of these lines. High-minded, industrious, accurate, and conscientious, he commenced the struggle of life at an early age, and by hard work, honesty, and perseverance with comparatively very small means, and independent of worldly influences, raised himself from the position of the once well-known "apprentice to a general practitioner," to that of the highest in a surgeon's ambition.

In private life his real worth was known to comparatively few. No one appeared to be more influenced for all that was right and good than he was. "Faith, Hope, and Charity" might be said to have been his guiding principles through a long life. No one gave more freely to a deserving cause; none but the giver knew to what extent; none but the receiver knew to what amount. Mr. Cæsar Hawkins was twice married, and has left a widow to mourn her loss, but no children.

J. W. MOORE MILLER M.D., M.R.C.P., J.P.

IT is with much regret that we record the death of Dr. J. W. Moore Miller, which took place at his residence, Southsea, on the 9th inst. Dr. Miller was the only son of the late Captain Miller of the 46th and 24th Regiments, and was born in 1820. He began his medical studies as a pupil of the late Mr. Caldwell, at Millbrook, near Southampton, where his father resided, and in 1838 entered at University College Hospital, where he was a dresser under Liston. After passing the College in 1841, he joined the Peninsular and Oriental Steam Packet Company, at first taking voyages between this country and Calcutta, and afterwards becoming superintendent medical officer of the Peninsular and Oriental Company's Bengal Station and Hospital. In addition to these appointments, during his residence in Calcutta he enjoyed a large private practice. Returning to England, he settled at Southsea in 1859, succeeding the late Dr. Engledue. In 1862 he was elected one of the staff of the Royal Portsmouth Hospital, an appointment which he held for five years. He was also consulting physician to the Royal Seamen and Marines' Orphan School, and medical referee for several insurance companies.

In 1863 Dr. Miller became a member of the Town Council, but, after a few years' service, finding that he was unable to devote sufficient time to the duties, he retired, or there is no doubt he would have been asked to accept the office of Mayor. He was placed on the Commission of the Peace in 1871. In the early days of the Portsmouth Artillery Volunteers, he held a commission as surgeon, and took considerable interest in all matters relating to the corps. From its formation he was a warm supporter of the Portsmouth Literary and Scientific Society, in which he had held the office of president, and was a contributor of papers on the Horse's Foot and Shoeing. On his return from a voyage to Australia, which he made in 1880, he gave the members an account of his experiences, and dwelt upon the desirability of utilising the Australian meat trade for the benefit of the residents in the mother country, and since then he patented some processes for the preservation of meat. He was the holder of a patent for anhydrous leather, to the improvement of which he had devoted considerable attention. Dr. Miller had shown signs of failing health for some months past, but continued in full work up to a few days before his death. Early on the 5th inst., he was suddenly seized with abdominal pain, which resulted in peritonitis; symptoms of cardiac failure became apparent, and notwithstanding the constant watching and care of his friends, Mr. H. Rundle and Dr. Wallace, he passed away on the 9th inst.

Dr. Miller was a man of strong force of character. In private life he was genial and most hospitable, and won the esteem and affection of his patients, by many of whom he was regarded as a trusted friend as well as medical adviser. In public, his skill and thorough practical knowledge, combined with his sound treatment of disease, had secured for him a large practice, and brought him into frequent requisition as a consultant. By his unvarying kindness and ready sympathy, he had endeared himself to a wide circle of friends, by whom his memory will long be held in high regard.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Monday last:—

Atkinson, Ambrose, Leeds.
Campbell, E. Kenneth, M.B. Edin., Wimpole-street.
Child, Herbert, L.S.A., Hedingley, near Leeds.
Graham, A. William, Cambridge-street.
Greenough, Edwin, M.B. Edin., Wibsey, Yorks.
Grimmer, C. George, L.R.C.P. Edin., Bungay.
Hanson, Alfred, Launceston.
Hepburn, David, M.B. Edin., Milnathort, N.B.
Hewer, Henry John, Highbury New-park.
Hoper-Dixon, Arthur, L.R.C.P. Edin., Ashford, Brecon.
Johnston, Benjamin Rigby, L.K. & Q.C.P.I., Ambleside.
Jones, Harry Shirley, L.S.A., Bromsgrove.
Lawson, Robert, Winthank, Fife, N.B.
MacConnel, Henry Wilson, M.B. Cantab., Girvan, N.B.
Mallam, L. George, M.B. Edin., Armidale, New South Wales.
Mason, Henry, Ulleskorpe.

Digitized by Google

Pockley, F. Antill, M.B. Edin., Sydney, New South Wales.
Purchas, A. Challinor, M.B. Edin., Auckland, New Zealand.
Simms, Henry, Stourbridge.
Spackman, Coniston, Faringdon, Berkshire.
Stiles, A. Jalland, M.B. Edin., Spalding.
Warwick, F. James, M.B. Cantab., Loughborough-road.
Welpton, John, Leeds.
Williams, Alfred, M.B., Glasgow.

Admitted Members of the College on Tuesday last:—

Blacker, Arthur Barry, L.S.A., St. George's-road.
Brown, David Matthews, M.B. Edin., Edinburgh.
Churcher, Thomas Gillard, M.B. Edin., Walworth-road.
Collins, Arthur Ward, L.R.C.P. Lond., Rainhill.
Crisp, James Ellis, L.S.A., Lacock, Wilts.
Fletcher, W. W. Ernest, M.B. Cantab., Argyle-square.
Hughes, Henry Milner, M.B. Durham, Harrogate.
Jefferies, Horace, L.S.A., Bromsgrove.
Jones, Richard Nelson, L.R.C.P. Lond., Swansea.
Keele, John Rushworth, L.R.C.P. Lond., Southampton.
Mirza, Jafarkuli Faredumbeg, L.R.C.P. Lond., Bombay.
Taylor, John Clesaley, M.B. Edin., Windermere.
Thurston, Hugh Champneys, L.R.C.P. Lond., Thornbury, Gloucester.
Walker, Edward, M.B. Edin., Huddersfield.
Welsford, George Frederic, M.B. Cantab., Winterbourne, Isle of Wight.
Whitelock, R. H. Anglin, M.B. Edin., Jamaica, West Indies.

Admitted Members of the College on Wednesday last:—

Beardmore, George Russell, L.S.A., Islington.
Bowden, Reginald Treacher, L.S.A., Tenbury, Worcester.
Bryden, Frederick, M.B. Durham, Melbourne.
Clarke, J. McFarlane, L.R.C.P. Lond., Bolton, Lancashire.
Earle, Cyril Somerset, L.R.C.P. Edin., Manchester.
Ferguson, James Haig, M.B. Edin., Edinburgh.
Gent, George Sidney, L.S.A., Bristol.
McDougall, James Edlington, L.R.C.P. Edin., Walton, Liverpool.
Quennell, Robert William, L.R.C.P. Edin., Brentwood.
Roberts, Edwin, Leeds.
Shackel, George Arthur, L.S.A., Reading.
Sharp, Charles John, L.R.C.P. Lond., Liverpool.
Trevor, Robert, L.R.C.P. Lond., Halsey-street.
Weston, George Henry, L.S.A., Bognor, Sussex.
Williamson, Richard Thomas, L.S.A., Burnley.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations held on the 30th ult. and following days, the undermentioned passed in Anatomy, Physiology, and Materia Medica:—

Alfred Barcroft, Alfred G. Beale, James C. Boyce, Thomas Browning, Alban Butler, Louis A. Byrne, Edward J. Cotton, Frederick G. Davis, Richard H. J. Fetherstone, Henry L. Finny, Arthur J. Gernon, Frederick Hall, Nicholas J. Harmon, Timothy H. Harrigan, John Keatly, Thomas Kidd, Richard J. Leper, Martin B. Lyster, Patrick T. Morrissy, Hugh S. Morrison, Samuel F. Murphy, Pierce J. J. O'Connor, James A. Sawyer, Davis D. Tate, George Woods, Ernest H. Tweedy.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 17th:—

Nutting, Philip Henry, Hasely Hall, Warwickshire.
Morgan, T. Whitworth Sewell, Roupell-park, Streatham-hill.
Preston, Francis Harrison, Ampton-street, Gray's-inn-road.
Shackel, Geo. Arthur, Erleigh-court, near Reading.
Soden, Thomas Armand Bourne, Newcastle-on-Tyne.
Staple, James Dibble, Hereford-road, Bayswater.
Wright, Sydney C. Ernest, Upper Kennington-lane, Vauxhall.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Ralph Holyoake and Bernard Volckman, London Hospital.

DR. EVANS, of the Lodge, Brymbo, who had practised as a surgeon in the locality for some years with marked success, was found yesterday morning burnt to death in a workman's cabin at Firwd Ironworks.

SANITARY HOUSES.—A conference was held on the 11th inst., under the auspices of the Royal Institution of British Architects, in the conference room of the Health Exhibition, on the Construction of Sanitary Houses. After an introductory paper on the subject of Sanitary Construction in general had been read by Professor T. Roger Smith, a paper was read by Mr. F. W. Hunt on the Sanitary Arrangements of Houses during the past 120 years, and another on Drainage under Dwellings by Mr. S. F. Clarkson. A discussion followed the reading of the papers.

VOLUNTEER AMBULANCE MOVEMENT.—An inspection of the bearer company of the St. Thomas's Hospital Ambulance Association was made in the grounds of Lambeth Palace on Wednesday last. The inspecting officers were Major-General Elkington, C.B., Deputy Adjutant-General, and Dr. Crawford, Director-General of the Army Medical Department. A numerous company were present, among whom were Lord Morley, Under Secretary of State for War; Surgeon-General Hanbury, K.C.B.; Dr. Billings; Mr. Ellisson, of the French Red Cross Society; Mr. Archibald Forbes; Professor Longmore, C.B.; Brigade Surgeon Nash; Surgeon-Major Roe; Surgeon-Major Evatt; Surgeon Cross; Mr. Cantlie; and Sir William Mac Connac, President of the Association. At the close of the drill, Dr. Crawford complimented the company on its performance, and remarked on the value of the movement as a means of providing properly qualified surgeons for the volunteer force.

AT a recent meeting of the Dover Town Council a scheme for extending the sewer outfalls and further improving the drainage of the town, consequent on the growth of the borough, was approved. The approximate cost of the scheme is about £10,000.

THE DRAINAGE OF HENDON.—A Select Committee of the House of Lords has passed a Bill, which has already received the sanction of the House of Commons, confirming a provisional order granted by the Local Government Board, to enable the Hendon Local Board to acquire by compulsion thirteen acres and a half of land at Hendon, for the purpose of enlarging their existing sewage works, and to deal with the sewage by chemical processes and by filtration. The effluent from the proposed works will pass into the river Brent, and the solid matter will be used as manure.

NATIONAL HEALTH SOCIETY.—At a meeting of the Vaccination Officers' Association, held on Saturday last, a cordial vote of thanks was given to the National Health Society for issuing their pamphlet entitled "Facts concerning Vaccination," and the Association expressed their appreciation of the "thoughtful kindness which prompted the Society to assist the vaccination officers of the metropolis in the discharge of their often difficult duties." The pamphlet in question has, we understand, now been distributed from house-to-house in most of the districts in the metropolis where small-pox is epidemic.

SOUTH LONDON SCHOOL OF PHARMACY.—The following were the successful competitors at the School examination held from the 26th of June to the 5th of July:—Senior Chemistry: medal, R. Wilkinson; certificates (equal), D. Arnott and J. Jackson. Junior Chemistry: medal, W. Rushton; certificate, W. Holme. Botany: medal, T. J. Clarke; certificate, R. Atkinson. Materia Medica: medal, W. Holme; certificate, T. J. Clarke. Pharmacy and Practical Dispensing: medal, F. E. Brown; certificate, W. Rushton. Extra certificates of merit: Messrs. Coleman, Cooper, H. Jackson, Kingan, Mathews, Taylor, Ward, and Williams.

SOCIAL SCIENCE ASSOCIATION.—At the annual business meeting held at the offices of the Association in Adam-street on Tuesday, a report from the Council, detailing the action taken by the Association during the twelve months ending June, was presented and ordered to be received and circulated. The report dealt with several subjects of interest in regard to which special action had been taken, and among these may be mentioned—milk-supply; loss of life at sea; the Hospitals Association, which was the outcome of the Conference on Hospital Administration held last year under the auspices and management of a special committee of the Council; and the International Health Exhibition. The Right Hon. G. J. Shaw-Lefevre, M.P., was appointed president for the year 1884-85, Dr. Norman Chevers being elected to preside over the Health Department with Mr. H. H. Collins and Dr. Edward Seaton as secretaries.

THE SANITARY ASSURANCE ASSOCIATION.—At the ordinary monthly meeting of the Council of this Association, on July 14th, a paper on the Sanitary Exhibits at the International Health Exhibition was read by Mr. Mark H. Judge, A.R.I.B.A. On the question of the disconnexion of house drains, Mr. Judge said arrangements for providing a free passage of air into drains on the house side of outfall traps to form an air break or disconnexion between sewers and house drains were now admitted to be necessary by all sanitary authorities. By means of the outfall syphon trap, combined with air disconnexion and outlet ventilation above the roof, a dwelling would be thoroughly protected from the ingress of sewer air. With perfect house drains properly disconnected from the sewer, the inhabitants of a town dwelling might enjoy the blessings attendant upon cleanliness; but without such disconnexion from the public sewer the cleanest possible household must share the dangers resulting from the sins of others against the laws of health.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ANDERSON, JAMES, M.D., M.R.C.P.Lond., has been appointed Medical Registrar to the London Hospital, vice C. F. Coxwell, M.B., M.R.C.P.Lond., resigned.

ARTHY, G. F. S., M.R.C.S., L.R.C.P.Ed. (late House-Surgeon to the General Infirmary, Leeds), has been appointed House-Surgeon to the Chorlton Dispensary, Manchester.

BROUGHTON, HENRY TODD, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Heckmondwike District of the Dewsbury Union.

CARNELLEY, MATTHEW, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Wilford District of the Basford Union.

CATTE, JAMES, B.C.Dub., has been appointed Medical Officer for the Pembridge District of the Kington Union, vice Wilson, resigned.

COUPE, JOHN QUILLER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fifth District of the Penzance Union, vice J. Quick.

GROVES, H. J. FIRTH, L.R.C.P.Lond., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the District of Manning River, N.S.W.

HARDING, THOS. MASSEY, F.R.C.S.Eng., has been appointed Government Medical Officer for the District of Ryde, N.S.W.

HILL, J. HIGHAM, M.D., F.R.C.S.E., has been appointed Government Medical Inspector for the United States of America at the Port of London.

HODGES, HERBERT CHAMNEY, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Watton District of the Hertford Union, vice H. B. Hodges, resigned.

KEMPE, JOHN ARTHUR, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the North Tawton District of the Okehampton Union, vice Norman, resigned.

PEARCE, WALTER, B.Sc., M.R.C.S., L.R.C.P., has been appointed Medical Superintendent to St. Mary's Hospital, London, vice Alex. Stewart Brown, F.R.C.S.Ed., resigned.

PRATT, W. SUTTON, L.F.P.S.Glas., L.S.A.Lond., has been appointed Medical Officer for the Third District of the Daventry Union, vice Swann, resigned.

QUICK, JOHN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District and Workhouse of the Penzance Union, vice J. R. Quick, deceased.

SPURGIN, W. H., M.R.C.S., L.S.A.Lond., has been elected Medical Officer of Health for the District of Maryport, vice J. Pearson, M.D., resigned.

TUCK, JOHN, M.R.C.S., has been appointed Medical Officer to the Tambo Hospital, Queensland.

WHEELER, D. M. BRUMWELL, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Union Infirmary, Chelmsford, vice D. Wheeler, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BUCHANAN.—On the 22nd inst., at High-street, Chatham, the wife of Arthur Buchanan, M.D., of a son.

GWYNNE.—On the 20th inst., at Brightfield House, Sheffield, the wife of H. Nelson Gwynne, B.A., M.B., of a daughter.

HALL.—On the 19th inst., at Laurel Villa, Victoria-road, Surbiton, the wife of Edgar A. Hall, M.B., C.M.Edin., of a daughter.

SCOTT.—On the 18th inst., at Carlton Villas, Colney Hatch, the wife of Hugh Scott, M.R.C.S., L.S.A.Lond., &c., of a son.

MARRIAGES.

HOLTHOUSE—HESKETH.—On the 17th inst., at St. John's, Redhill, Surrey, Edwin Hermus Holthouse, M.A., F.R.C.S., second son of Casseton Holthouse, F.R.C.S., to Harriet Emily, eldest daughter of the Rev. Robert Hesketh, Esq., of Earlswood Mount, Redhill.

MCTAVISH—HOOPER.—On the 16th inst., at the Parish Church of Claines, Worcester, Alexander Campbell McTavish, Brigade Surgeon (retired), son of the late Rev. A. McTavish, of Inverchoalain, Argyleshire, to Mary H. Katherine, second daughter of A. C. Hooper, Esq., The Grange, Claines, Worcester.

DEATHS.

GODFREY.—On the 12th inst., at Epsom, Race Godfrey, M.R.C.S., formerly of Bath, in his 92nd year.

HAWKINS.—On the 20th inst., at Grosvenor-street, Cæsar Henry Hawkins, F.R.S., F.R.C.S., and Serjeant-Surgeon to the Queen, in his [illegible] year.

KNAGGS.—On the 17th inst., at Camden-road, N.W., Henry Knaggs, [illegible], aged [illegible].

MORRIS.—On the 11th inst., Henry Morris, F.R.C.P.Ed., late 6th Royal [illegible] and 7th Dragoon Guards, aged 45.

[illegible].—On the 17th inst., at Ashton House, Steeple Ashton, Job [illegible] Seale, M.D., aged 83.

TAYLER.—On the 12th inst., at Bradbourne House, Acton, Charles Alfred Andrews Tayler, M.R.C.S., aged 22.

N.B.—A fee of 2s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE DRAINAGE OF SHREWSBURY.

A CORRESPONDENT writes that a good work would be accomplished if the people of Shrewsbury could be persuaded to direct their drainage from the Severn. He states that the fine old town is rendered a disgrace to civilisation, and that on a recent visit to the place, the water being low, six or eight discharge pipes were visible, emitting fæcal matter with great rapidity. His remonstrance to a friend elicited the reply that "the next storm would clear it all away." This water, filtered, forms the chief supply for all purposes when it reaches Worcester! He was informed that typhoid exists in Shrewsbury at the present time.

PURE OR IMPURE?

To the Editor of THE LANCET.

SIR,—On the coast a large fishing village is partly divided by a brook or beck, which commences amongst the hills a few miles distant, and flows into the sea a little below the village. This beck has been the water-supply of the inhabitants for centuries, and still provides the only water for drinking and all domestic purposes. There are several respectable residents—some shipowners, captains' families, and others.

It has been decided by the local board of a village about two miles distant to carry a drain the whole length of their village, and then, by a descent, to convey the contents into a branch stream, which flows onwards, passing into the waters which go on to the first-named village. This drain is to carry all offensive matters from the waterclosets, privies, pigstyes, slaughterhouses, and other impurities. Their present medical officer of health states that the sewage matters will have about two miles to flow, and cannot in any way tend to deteriorate the "pure water." There is something exceedingly repulsive in the idea of such proceedings.

Will you please state if such a course is justifiable, and whether the filth will not tend to make the waters unfit for use.—Yours truly,

July 14th, 1884. ONE INTERESTED.

*** The arrangement as described will be in violation of the Rivers Pollution Act, and it will also be unjustifiable. The purification which it is alleged will take place is denied by the Rivers Pollution Commissioners, and appeal should be made to the Local Government Board against the contemplated works.—ED. L.

"A TAILED CHILD."

To the Editor of THE LANCET.

SIR,—With reference to the above subject, which appeared in your issue of July 5th, p. 46, I think those interested in the subject may find several well authenticated cases noted in the Medical Digest, section 3: 5.

I am, Sir, yours truly,

RICHARD NEALE, M.D.Lond.

Boundary-road, N.W., July 18th, 1884.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

AT the examination for the Membership, on July 18th, the following were the questions put in Surgical Anatomy and the Principles and Practice of Surgery, four of which were required to be answered:—

1. Mention the several structures which must be divided in removal of one-half of the inferior maxilla.
2. Describe the ligaments of the hip-joint, and state how they are affected in dislocation upon the dorsum ilii.
3. Describe the treatment you would adopt in a case of extensive lacerated wound of the scalp, and mention the evil consequences which may follow this injury.
4. Describe the varieties of keratitis.
5. State the various complications of fracture of the ribs, and their treatment.
6. Mention the complications that may occur in the course of gonorrhœa in the male and female respectively. Explain their modes of origin.

On the 19th, answers to three of the following questions on the Principles and Practice of Medicine were required:—

1. Discuss the symptoms and production of general dropsy, indicating the causes on which it may depend, the manner in which the several varieties can be distinguished, and the treatment called for in different circumstances.
2. What are the causes and symptoms of Bell's paralysis, or paralysis of the portio dura? Point out the distinctions between this condition and the paralysis observed in hemiplegia.
3. What are the causes, signs, and symptoms of pneumothorax?
4. State the therapeutical effects of the following drugs, and mention their officinal preparations, and their doses when for internal administration: silver, lead, zinc, antimony, digitalis, colchicum, belladonna, and stramonium.

The questions on Midwifery and the Diseases of Women were as subjoined, answers to three of them being compulsory:—

1. Describe the mechanism of labour with the child in abdomino-anterior position and the breech presenting.
2. What means would you adopt with a view to prevent hæmorrhage after labour?
3. What is meant by concealed accidental hæmorrhage? What are its symptoms, and how would you treat it?
4. What conditions produce enlargement of the cervix uteri? How would you distinguish between them?

A CASE OF CHOLERAIC DIARRHŒA.

To the Editor of THE LANCET.

SIR,—On Sunday, the 13th inst., I was called to see G. B——, a married man, aged twenty-nine. I found him suffering from profuse watery diarrhœa and vomiting, with coldness of the extremities, cramps in the abdominal muscles and in the calves of the legs, and symptoms of collapse. He said he was quite well in the morning, and partook of a dinner of roast beef, potatoes, peas, and Yorkshire pudding, with beer. After dinner he laid down and slept for two hours and a half. On awaking he felt an inclination to go to stool, and on going to the closet a profuse watery motion of a yellowish-white colour "ran from him for ten minutes like a tap," without pain. The attacks of purging recurred every few minutes until he became so weak in two hours that he was unable to get up without fainting, and vomiting set in, with cramps in the bowels, and in the calves of the legs and soles of the feet. I ordered a large mustard plaster to be applied over the whole of the abdomen, and kept on as long as it could be borne, and gave half-drachm doses of a 1-in-20 solution of carbolic acid (B.P.), 15-minim doses of the solution of morphia, and 20-minim doses of the aromatic spirit of ammonia, in an effervescing mixture, every two hours. I also ordered a diet of soda-water and milk exclusively. The first dose gave relief to the cramps, and stopped the diarrhœa and vomiting. In six hours he felt comparatively well, and by the time six doses had been taken he was able to come down stairs, feeling all right, except for a little weakness of the legs.

I am, Sir, yours faithfully,

Clayton-le-Moors, July 20th, 1884. C. R. ILLINGWORTH, M.D.Ed.

KOUSSINATE OF SODA.

G. B. B. desires to know what is the dose and the best form in which to prescribe the koussinate of soda.

Incognito.—We do not think the present state of our knowledge of the subject would support the ideas entertained by our correspondent.

THE PINK FUND.

To the Editor of THE LANCET.

SIR,—The following additions to the above Fund have been received up to July 23rd:—H. de Vaux Balbirnie, Esq. (Walkley), £1; J. L. Jardine, Esq. (Capel Docking), 5*s.*; R. Palgrave Simpson, Esq. (Weymouth), 10*s.*; A. J. (Matlock), £1; Anonymous, (Warminster), 10*s.*; Thos. Smith, Esq. (Stratford-place), £3 3*s.*; W. R. Parker, Esq. (Liverpool), 10*s.*; Francis Walmesley, Esq. (Belmont), £1 1*s.*; Francis Vacher, M.D., £1 1*s.*; A. J. Newman, Esq. (St. Martin's, Bowness), 10*s.*

I am, Sir, yours truly,

Soho-square, July 29th, 1884. JOSEPH ROGERS.

Durham.—Both are good. The prestige of Durham is, of course, not equal to that of the other university mentioned.

NON-PAYMENT OF A LOCUM TENENS.

A CORRESPONDENT sends us a curious account of his failure to get any payment from a practitioner whom he had served faithfully as a locum tenens during a long and somewhat mysterious absence. He has been at much expense to enforce payment of his claims. But law has not helped him. He should persevere, and, failing, place the facts before the Medical Council. He has reason to think that others have been similarly treated.

An Old Assistant will see that we have dealt with Sir Lyon Playfair's statements in a separate annotation. Our correspondent is a little shocked at Sir Lyon's representation of the risk of medical men not being forthcoming in sufficient numbers (as he well may be); but some sentences of his letter are a little too warm.

THE WHEATLEY MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—The committee of the Wheatley Memorial Fund have now closed the subscription list, and have desired me to announce a final list of donors, which I shall be obliged by your inserting in your next issue. The committee also authorise me to beg leave to publish the balance-sheet of the treasurer of the Fund, and to inform the subscribers that the treasurer has handed over to the beneficiaires of the Fund, after paying expenses, £804 6*s.* 1*d.*, in the proportion of two-thirds to Miss Maria Wheatley, the sister, and one-third to Miss Mary Caroline Wheatley, the niece, of the late Mr. B. R. Wheatley.

I am, Sir, yours faithfully,

Berners-street, W., July 21st, 1884. BERKELEY HILL, Hon. Sec.

STREET PAVING.

To the Editor of THE LANCET.

SIR,—At the present season, when the imperative necessity of immediately removing anything which may contaminate the atmosphere appears paramount for the dissemination of the germs of disease is fully recognised, is it not much to be desired that our streets, and especially our back streets and slums, should be more generally paved with some material, such as asphalte, which, being non-absorbent and impervious, cannot retain any liquid impurity, while its perfectly smooth and level surface is not only washed down by every shower of rain, but, offering no obstruction to the free action of the broom, is kept perfectly clean with the greatest ease, preserving the atmosphere in sweet and wholesome condition?

I am, Sir, your obedient servant,

July 17th, 1884. SANITAS.

W. B. Holderness.—It would depend upon the relative amount of Condy's fluid and stout in the mixture. If the stout were in excess it would reduce all the permanganate to the state of oxide. In that case the remaining organic matter should be destroyed by hydrochloric acid and chlorate of potash, and the usual tests for manganese then applied. If there is any permanganate remaining in the original mixture, the liquid should be saturated with carbonate of potash, filtered, the process repeated, the filtrate evaporated, and examination be made for crystals of potassic permanganate.

Mr. Roocroft.—Next week.

EXCISION OF SPINA BIFIDA.

To the Editor of THE LANCET.

SIR,—I beg to report a case of successful excision of a spinal hernia, upon which I operated a short time ago.

A child aged fourteen days was brought to my surgery, suffering from a spina bifida, the hernia being about the size of a pigeon's egg, situated over the fourth lumbar vertebra. It was covered by the whole thickness of integuments, having a narrow base, tense and elastic, and becoming very much more so when the child cried. There was no incontinence of urine or fæces, nor paralysis of the lower limbs, the child being healthy and well developed in every other respect. I explained to the mother the great danger there might be in interference, but she particularly desired, as she expressed it, "to have something done for the child." Having cautioned her again as to the possibility of the child dying immediately of convulsions, I proceeded to tap the tumour with one of Dr. Southey's trocars and cannula, and drew off about two drachms of spinal fluid. I then injected fifteen drops of the tincture of iodine with forty-five drops of water, afterwards applying a compress over the hernia, and sent the child home, with instructions to return in a couple of days, it being none the worse for the first tapping. I repeated the injection a second time, but of a strength of equal parts, again applying the compress. On the child presenting itself the third time, I was pleased to find a diffused inflammation over the parts and a decided contraction of the tumour, and was able to make pressure over the hernia without causing any symptoms of convulsions, which led me to believe there were no important nerves implicated. I therefore injected a drachm of tincture of iodine (B.P.), having previously drawn off a like quantity of spinal fluid; and having tightly compressed the parts, I once more told the nurse to bring the child in a couple of days, at which time I found the hernia contracted to the size of a cherry. I now applied a clamp, specially made for the case by Messrs. Woods of York, with the intention of closing the neck of the sac, yet not sufficiently tight as to interfere with the circulation, and each day I continued to tighten the clamp. On the fourth day, with a sharp bistoury I cut off the tumour, when there was some little hæmorrhage. I therefore simply tightened the clamp, and left it in position twenty-four hours longer, when I removed it, and was pleased to find the opening between the spinal column and the tumour entirely obliterated. From first to last the child never showed a bad symptom resulting from any portion of the operation, sleeping and taking the breast well.

I am, Sir, yours truly,

Snenton, Nottingham, July, 15th, 1884. ROBT. HOWSON.

Mr. S. H. Little.—The case would be very remarkable only if the two spleens were of equal, or nearly equal, size.

THE ONTARIO PUBLIC HEALTH ACT.

To the Editor of THE LANCET.

SIR,—Will you allow me a brief space to make a few remarks regarding the notice of the Ontario Public Health Act of 1884 which appeared in your issue of May 10th? I would have made this request earlier had I not been absent from home.

Your review, while on the whole favourable, takes exception to the "soil-pipe going up inside the dwelling, instead of in a chase outside." The reason for this you anticipate in your reference to the climate. It has been found by experience that we cannot run soil-pipes on the outer side of house walls in this country, or the northern portion of the United States. You may have some idea of the effects of our long-continued frost when you are informed that the ground freezes solid to a depth of over three feet. When we have thaws in the day-time and keen frosts at night we have trouble even with our rain-pipes. You would hardly imagine this from the reports of our bright, pleasant climate; the atmosphere is bright and dry, but there is long continuance of sharp frost at times. When you object to the soil-pipe being inside the house at all, you will *a fortiori* endorse the necessity there was for legislative enactment providing that all such soil-pipes should be continued up through the roof, and should have an outside ventilator allowing a current of fresh air to circulate through the drainage system of the house. The same reasons account for the difference in the treatment of the bath waste-pipe. The ventilation of drains at the ground level I consider dangerous; I have frequently seen such ventilators acting as outlets. I am glad to say as regards the ventilation of sewers on the level of the road-bed, that no less an authority than Mr. Sedgwick Saunders, through the medium of THE LANCET, pointed out some time ago the evil results arising from this practice in certain instances. You will find further arguments against this plan of drain and sewer ventilation, and in support of overhead ventilation of sewers, in a paper on that subject read by me before the American Public Health Association, and published in our second annual report, of which paper I send you a copy.

I am, Sir, yours truly,

Toronto, June 30th, 1884. WM. OLDRIGHT.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

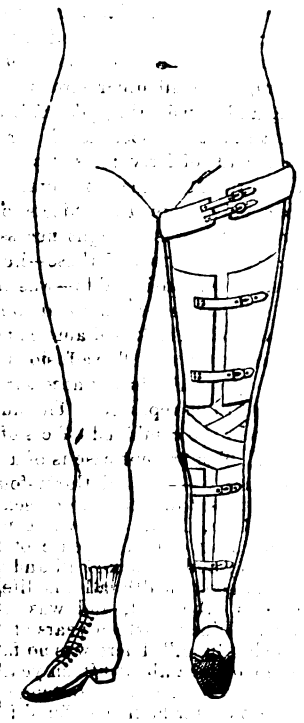
Clinical Lecture
ON
CHRONIC JOINT DISEASE.



BY RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON TO CHARING-CROSS HOSPITAL.

GENTLEMEN,—When last I addressed you on the subject of joint disease, I called your attention to a certain mode of treating acute synovitis by means of emptying the distended sac. I now wish to say a few words to you concerning the management of chronic articular disease.

In its earlier phases, while cure with perfect conservation of movement is possible, that termination should always be aimed at, and may very often be attained. The forms of malady which are most common, and to which I now more particularly refer, are those which attack children from one year to twelve or even fourteen years of age, and which very generally are combined with a strumous or scrofulous habit of body. Now, please pay especial attention to this. These diseases, although arising in strumous children, are very rarely indeed tubercular in origin. Struma is a certain habit of body, a certain faulty method of forming and nourishing its tissues, which, thus produced and sustained, are not diseased, but are apt to respond to any slight irritation by sluggish and prolonged inflammations, the immediate products of which have little or no tendency to higher development, but rather to certain forms of degeneration—suppurative, fatty, caseous, and tubercular. In certain parts of the body tubercle appears with great facility, therefore very frequently; in other parts with very great difficulty; and among these parts the synovial membrane is pre-eminent. I would not give you to understand that in joints long the subject of chronic strumous inflammation tubercle is never to be found; but when so found, it is tubercle not of synovial membrane, but of old inflammatory products. Contrast this with the mode of tuberculosis in internal organs, as, for instance, lungs; in them tubercle appears simultaneously, or almost simultaneously, with some very slight inflammatory change of tissue; it is impossible to say whether the deposit of some minute tubercular element is or is not the origin of the disease. Such a state of things is never found in a synovial membane nor in the joint end of a bone; in those parts tubercle, if it appear at all, is a late production—the terminal, and not the initial point of a morbid process.[1] These distinctions are not mere pedantic hair-splitting; they underlie, in fact, the question whether treatment of strumous joint disease is of any great value; for if such disease were the result of tubercle, the assertion, made a minute or two ago, that cure may be often attained, would be false. Were we not here in England restricted from the most valuable of all modes of pathological research, I believe I should be able to put this question at rest; as it is I must limit myself to examining certain experiments made in Germany with tuberculous materials.

"Dr. Schüller of Greifswald injected such matters into the lungs of twenty-four animals (dogs and rabbits), and at the same time, or very shortly after, severely injured the right knee-joint by blows with a mallet. Of these injured joints only six showed some spots, the most characteristic of which are described as "perhaps initial tubercle," and some as "heaped-up epithelioid cells," and "colossal giant cells," and this although in nearly all these animals the internal organs were thickly beset with tubercle. There is, in fact, no doubt that these creatures were thoroughly tuberculised; yet with such difficulty do joint structures admit of tuberculisation, that no instance of typically characteristic tubercle could be found in the injured joints. But more than this, although several of these animals died of what might almost be called tubercular intoxication, not a single uninjured joint out of the 264[2] showed any trace of tubercular affection. Whence we must conclude that a tubercular state of body does not produce joint disease—in other words, the earlier phases of chronic joint disease are not tubercular. Therefore, gentlemen, we will take it that the cases I show you are strumous but not tuberculous, and therefore we may assume that under favourable circumstances they are curable. It is now my business to tell you how to make the circumstances favourable and how to utilise them for your patient's benefit.

First, then, you will have to make out whether the malady originates in the bone or the synovial membrane. It is in the first stage of joint disease quite easy to do so, and I have again and again explained to you how this is to be done. We need not now occupy our time on that subject; though, as you will shortly see, several important points of treatment depend on the diagnosis. In either bone or synovial malady you have to do with a remarkably obstinate disease, whose sluggish character depends upon a state of bodily malnutrition which we call struma, and one of the first essentials towards improving this condition is to abstain from confining the children to one room or ward, or still more to bed, but to give them plenty of fresh air and exercise. When the affected joint is one of the upper extremity this is easy; but if it be one of the lower some difficulties present themselves, for we must so manage that, while moving about, the diseased joint is kept at complete rest, and that no weight be thrown on the joint surface. A large number of splints to carry out these indications have been invented. I have used at different times Taylor's, Sayre's, Thomas's, and others, but the apparatus which above all others I prefer is one to which my attention was called by Dr. von Wahl of Derpat, and which was invented by Dr. Dumbrowski of that university. It is thus made for the knee: To the knee segments above and below the joint poroplastic felt or leather is carefully moulded by hand and bandage; while these are hardening the sound limb is placed with its posterior aspect on a piece of paper, and a tracing is made of its inner and outer aspects. The circumference of the top of the thigh is taken in an oblique direction—i.e., from the perineum to a point a little above the great trochanter. Now the splint-like moulds are removed, and the rest is done by the instrument-maker. He bends two flat bars of steel or of iron (plate gauge No. 10 or 16), about three-quarters of an inch broad, to the shape of the tracings, only with a larger divergence at the knee, and taking care that they are about two or two and a half inches longer than the limb. These are to be riveted to the poroplastic or leather, which are likewise to be provided with straps. The upper end of the bars are made fast to an ischio-iliac ring, well padded and provided in front with a hinge and flap. Their lower ends are fastened by a pivot joint to a sufficiently large plate that underlies the sole. If instead of the knee the ankle is diseased, the splint is to be modified thus. A poroplastic socket is moulded on the foot and rendered motionless by a strap riveted to the metal uprights, while hinges are introduced in the iron opposite the knee, so as to permit free movement of that joint.

Now, to put on this appliance, the felt or leather sockets are to be softened again, the flap arrangement of the ischio-iliac ring is to be opened, the limb is easily introduced, the various straps are tightened, and the patient left at rest till

[1] Neither must we take every non-vascular spot containing one or two giant cells in the midst of old granulation tissue to be tubercle; certain points are, by the very mode in which that tissue is formed, excluded from the direct area of circulation; and wherever from such cause nutrition becomes defective, giant cells are apt to form, and these in their growth push aside and somewhat flatten the surrounding cells.

[2] That is, reckoning three joints to each of the ninety-six limbs and subtracting twenty-four for the injured right knee of each animal.

Digitized by Google

the rockets have hardened.[3] In a day or two a high shoe is to be provided for the sound limb so as to make it of the same length as the splint, and the patient must be taught to walk slowly at first, and probably with crutches. These he soon learns to discard, and to walk with surprising facility and comfort, and with arms perfectly free for any occupation or amusement. Observe that no motion can possibly take place at the joint, nor can any pressure of the body weight fall upon it; in fact, the diseased joint is at perfect rest, while the remainder of the body is in good exercise. Moreover, the surface of the articulation is uncovered, permitting any desirable treatment; but I see that I must defer these considerations to another very early opportunity, when I shall again refer to the subject.

ENDOCARDITIS COMPLICATED BY TUBERCULAR PLEURISY (WITH EFFUSION).[1]

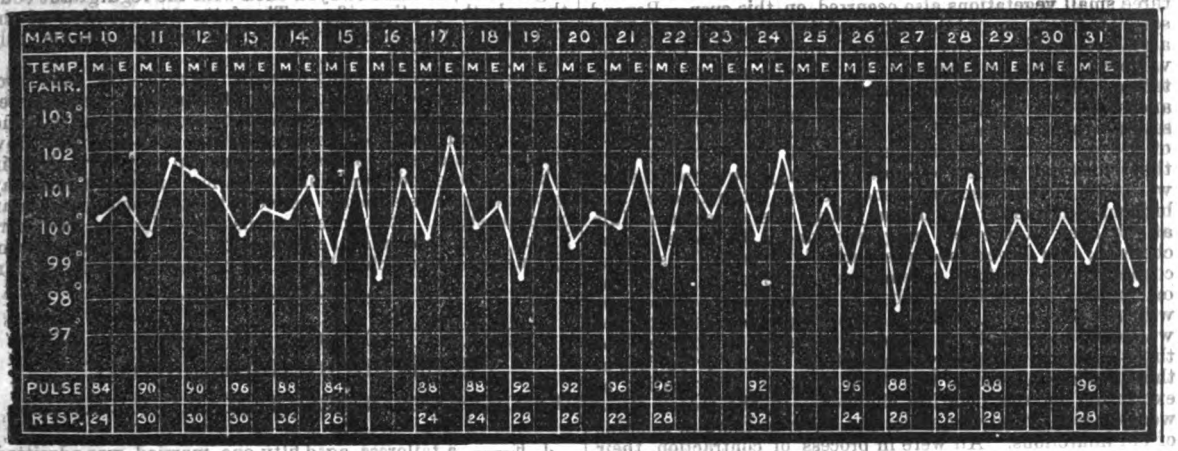
BY SIDNEY COUPLAND, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

IT would be a bold assertion to make that pleurisy does not commonly complicate chronic valvular disease of the heart, and I am not prepared to make it. The case is, however, I think, different with pleurisies which lead to large effusion, and far more important, because of the interference with the heart's action they produce. Setting aside the dropsical accumulations of fluid which occur in the pleura, as in all other serous sacs, in advanced cardiac disease, and considering *pleuritic* effusions only, I can safely assert that the association is rare. For on glancing through the records of forty cases of pleurisy with effusion under my care at the Middlesex Hospital during the past seven years, three only were in subjects of chronic cardiac disease. Paracentesis was thought necessary in twenty-two of these cases; and in two of these—i.e., cases in which mostly the effusion was considerable—was there heart disease present. One was the case I am about to relate. The other was in an old man with thickened aortic and mitral valves and general arterial atheroma. The effusion in his case was hæmorrhagic. Tapping was absolutely necessary for the relief of dyspnœa, and had to be repeated. The fluid became purulent, and he died from the combined effects of exhaustion and his cardiac lesion. The present case is of a different class.

Samuel S——, aged thirty-four, single, a house painter, was admitted into the Middlesex Hospital under my care on March 10th, 1884. He was complaining of a troublesome dry hacking cough, a sense of tightness in the chest and coldness; and he looked ill and worn. He said that he had enjoyed good health all his life, except that he was very liable to take cold, and was frequently troubled with a cough. When thirteen years of age he had "inflammation of the left lung." There was no family history of tubercle. He had gonorrhœa about fifteen years ago, but never contracted syphilis. His habits were temperate. During the whole of the past winter he had suffered from a cough, which a month ago became worse, and after one paroxysm he spat up a small quantity (about two ounces) of blood. At the same time he had been troubled with night sweatings. He seemed to lose sensation on the left side; he experienced a dull heavy feeling, "like a piece of wood" he expressed it, varied by attacks of sharp cutting pain over the lower ribs on exposure to cold. He had further been growing progressively weaker and losing flesh. He was a man of sallow complexion, unhealthy aspect, moist skin, and ill-nourished. Examination of the chest revealed a marked difference between the two sides. Thus, the left front was decidedly flatter than the right, which appeared abnormally bulged; and the inspiratory expansion was much less on the left than on the right. On percussion over the left front, resonance was impaired, merging in the axilla to absolute dulness. The right front and axilla were fully resonant. There was no appreciable difference, however, in the degree of vocal fremitus. The breathing was harsh, with prolonged expiration over both fronts and in right axilla; but in left axilla it was weak. A few scattered rhonchi were also audible. Over the back the contrast was more marked, the left being absolutely dull throughout and the right resonant. The dulness did not vary with position. Vocal fremitus was wholly absent over the lower half of the left back. The breath sounds were harsh, expiratory murmur prolonged and masked by sonorosibilant rhonchi over the right back; faint but somewhat bronchial in character over the left back, particularly at the angle of the scapula, where the breathing was intensely bronchial. At this spot also the vocal resonance was ægophonic. The heart's apex beat could not be defined, but a faint wave of pulsation was visible at the epigastrium. The carotid and subclavian arteries pulsated violently, and the radial pulse was collapsing but regular (84). The area of cardiac dulness began above at the third interspace, and did not extend beyond the left border of the sternum; outwards it merged in the axillary dulness. At the apex a soft systolic bruit was audible. At the second right (or aortic) cartilage was heard a well-marked blowing systolic bruit and a musical diastolic murmur. Both these murmurs were traceable down the sternum; and the systolic one could be heard in the carotids, where no second sound was audible. The pulmonary second sound was plainly developed at the third left cartilage and at the apex. The abdominal walls were tense. The hepatic area of dulness was normal, and the splenic margin could not be felt. The urine was high-coloured, turbid, with copious deposit of lithates; sp. gr. 1031, free from sugar or albumen. The expectoration was scanty and mucoid. The temperature ranged from 100·2° to 100·8° (evening).

The diagnosis was: aortic valvular disease, causing both obstruction and regurgitation, and, from entire absence of second sound in the carotids, probably of considerable degree; slight mitral regurgitation, possibly secondary to the aortic disease; pleurisy, with effusion on the left side of some standing, and consequent compression of lung; compensatory emphysema and slight bronchial catarrh on the right side. An exploratory puncture on the 11th was made with a hypodermic syringe, and the presence of a serous effusion in the left pleura was confirmed. The temperature during the next two days was above the normal, and from 1° to 2° higher in the evening than the morning. On the 12th breathing was rather laboured (30); pulse 90, regular; and he complained of being faint. He had been prescribed a mixture containing iodide of potassium, ipecacuanha, and squill. On the 13th, as he again showed a tendency to syncope, and the physical signs indicated no diminution in the effusion, it was decided to withdraw the fluid, and in order that this might be done with the least amount of disturbance to the heart, one of Southey's fine trocars was introduced into the chest in the sixth interspace, mid-axilla, and the fluid allowed to flow through a fine tube. By this means sixty-seven ounces of rather high-coloured serum were withdrawn in the space of two hours and forty minutes, when the flow ceased. He was greatly relieved by the tapping, having complained much during the previous night of the pain and pressure in the left side, which now ceased to trouble him. The next day it was noted that although the cardiac sounds were louder and the murmurs unaltered, the apex beat, hitherto obscured, was appreciable in the fifth interspace, an inch and a quarter below and one inch within the nipple. Over the left back resonance had returned as far as the angle of the scapula, but below that point and in the axilla dulness persisted. The ægophony had disappeared, but bronchial breathing remained, and in addition some fine friction sounds could be detected in the axilla. The breathing was easier and the cough lower. The skin was moist, and he still had some sweating at night; the temperature still maintained a level of about 99° in the morning and 101° at night. (See Chart.)

There is no need to enter fully into the daily detail of the case, which remained for some time in a stationary condition, the signs pointing to a certain amount of reaccumulation of fluid, the dulness and bronchial breathing never clearing up, and the sense of constriction being again complained of. In fact, there was no evidence of re-expansion of the lung, but rather of a slowly continuous contraction; for on the 25th it was noted that the gastric resonance reached as high as the seventh rib in the axilla, the epigastric pulsation of the heart was also plain, and the apex beat had undergone no change in position. Vocal fremitus had slightly returned over the left back, and the friction rales had mostly gone. Moreover, his cough remained very troublesome, and had assumed a clanging



[3] If the joint have become bent, it must be straightened after the manner to be hereafter described.

Digitized by Google

character. It was further noted that the systolic murmur at the aortic cartilage was followed by a sharp sound, the diastolic bruit being almost inaudible, but heard at the mid-sternum from the third to the fifth cartilages.

On April 3rd, in spite of inhalations and sedatives, the cough troubled him a great deal, and also the constriction across the chest. Examination failed to detect any additional signs, certainly nothing to suggest the presence of a deep-seated thoracic aneurysm, or other source of pressure on the air-passage exciting the cough. Dr. Finlay, who took charge of the ward later, made a laryngoscopic examination with a negative result. The temperature chart still showed the same character of continued pyrexia, but there was no appreciable increase in the loss of flesh. The friction sounds had returned, and were heard during the remainder of his stay in the hospital; at first fairly universal, they became gradually limited to the axillary region. It was to the persistence of this pleurisy that was attributable the stabbing pain in the left shoulder complained of from April 20th to the 23rd. On the 24th it was noted that over the left back there were still dulness and diminution of vocal fremitus; fine friction sounds were also audible. The breathing was no longer bronchial, but towards the left axilla it became harsh, with prolonged expiration. As to the cardiac signs, it was again observed that the diastolic bruit, which had lost its musical character, was best heard over the sternum, about the third cartilage. Also that the soft systolic bruit at the apex was conducted towards the axilla. He had now been on tonics for about a week, and he was allowed to get

up for a short time, and his diet was increased. Although he remained anæmic and sallow, and still complained at times of a dragging pain in the left chest, his general state so much improved that I sent him to a convalescent home. He left the hospital on May 15th; the dulness over the left lung, except at the apex and in front, not having altered, the breath-sounds remaining weak and distant, and friction being still audible. Vocal fremitus was increased over the left front, diminished at the back; but vocal resonance was there in excess. The cardiac condition was unaltered.

I may pause here in the record to explain the view that one was almost compelled to take from the inveteracy of the pleurisy and the accompanying pyrexia. In the first place, it was tolerably clear that the pleurisy had no connexion with the cardiac disease. When and how the valve mischief originated it was not possible to say, nor indeed could a date be positively affixed to the attack of pleurisy. At any rate, the onset of the latter must have dated back many months; and it was probably partly an increase in the effusion as well as his growing debility, which led him to seek admission into the hospital. The fact that the lung did not re-expand to any marked extent after the removal of the fluid was confirmatory of this view, which was further borne out by the persistence of the dulness and enfeebled breathing to the very end.

There can be no question as to the need of paracentesis here. In the presence of grave valvular disease the existence of pleuritic effusion, especially on the left side, is a serious complication. And it seemed that the diseased heart was being embarrassed by it in this case. The withdrawal of upwards of three pints of fluid from the chest under these conditions could not but have been beneficial; and the relief obtained was for the time very marked. The cardiac disease, which eventually caused the death of the patient, did not at this time give rise to much anxiety. I confess that I was most concerned then with the pleural affection, which obviously seemed not to be a simple pleurisy. The persistence of the friction showed that the inflammatory process had not terminated in universal adhesion, and suggested that it was still continuing. Chiefly, however, the thermometric curve determined me to believe that the pleurisy was probably of tubercular character, an idea quite in accord with the history of the case, so far as the progressive emaciation and sweating were concerned, and the history of an attack of inflammation of the lungs in early life. Against this view was the absence of any family tubercular taint, and, what was more important, the entire absence of any evidence in the patient himself of pulmonary tubercle, unless the somewhat persistent bronchitis and the troublesome cough could be so explained. Believing, however, that a continued pyrexia of a somewhat hectic character, extending over weeks in duration, is one of the most important elements in determining the tubercular character of a chronic inflammation, I could think of no other alternative. Nor did the fact of his improvement in general health, sufficient to allow of his discharge, entirely dispel this notion, for when he left the hospital the pleuritic signs still persisted.

The rest of the case is unfortunately only too briefly told. He appeared at the hospital on June 5th, after his return from the convalescent home, looking none the better, but rather the worse, for his sojourn. He said that he had been suffering much from cramp in the legs, and that his cough still troubled him. An examination of the heart revealed a slight change in increased intensity of the systolic apex murmur, and of the diastolic basic, which was now inaudible over the aortic cartilage, but hardly heard over the pulmonary—i.e., to the left of the sternum. The condition of the left pleura was not apparently altered.

I regret that the patient was not then readmitted, for he returned a week later in a state of great prostration and dyspnœa. He said that for the last four days he had been unable to take food, and that he was extremely weak and feeble, added to which he was suffering from prolapsus ani of three days' standing. There was a slight rally from the collapse, under stimulants, including hypodermic injection of ether, and he recovered sufficiently to take some nourishment. The pulse, which was very rapid and thready when he was admitted, gained in force and volume. The rally was, however, delusive, for at 2 A.M. next day he was seized with pain at the heart, and fell back dead. Some urine which he passed before death was highly albuminous.

The post-mortem examination was made by Dr. J. K. Fowler, twelve hours after death, and his report is as follows:

"The peritoneal cavity contained fourteen ounces of slightly turbid serum; membrane normal. There were dense fibrous adhesions over the greater part of the left pleura, less firm at the apex, and incomplete over the posterior surface of the lower lobe, where there was still some fluid between the layers, which were here nearly three-sixteenths of an inch in thickness. Over the upper lobe both layers were studded with fine miliary granulations. These

Digitized by Google

could not be distinguished below, probably owing to the thickness of the pleura. The costal pleura was removed with the lung, and its outer and posterior surface was marked by ridges corresponding to the intercostal spaces. There were no adhesions on the right side, but eight ounces of fluid. The pericardium was normal. The heart weighed 18 oz.; the right cavities were distended with mixed clot and fluid blood. The muscular tissue was marked by pale yellow fatty striæ; the valves were normal; the left auricle was not dilated; the mitral valve was slightly contracted at its free edge, near which, on the anterior cusp, were some fine fibrinous vegetations, which also occurred around some of the chordæ tendineæ near their insertion in the valve. Two aneurysms existed in this cusp: one three-sixteenths of an inch from the free edge had a perforation, one on each side, and a very small sac; the other higher up, a little above the centre of the cusp, projected on the auricular aspect in the form of a sac, the size of a pea, surmounted by a small diverticulum. On the ventricular aspect of the cusp the ulcerated mouths of these aneurysms were to be seen, the larger having smooth and rounded margins. Above and below this the valve was covered with a layer of minute vegetations as well as erosions, excited apparently by friction of the aortic vegetations, for the aortic valve was much diseased. Its middle cusp was in great part concealed by a warty mass of vegetations, embedded in which were concretions of lime salts; the right coronary cusp was much reduced in size, i ts free margin deeply eroded and ragged; the left cusp retained the normal shape, but was opaque and infiltrated with calcareous matter near its attachment; two or three small vegetations also occurred on this cusp. Beyond some atheroma around the orifices of the coronary arteries, the aorta presented a perfectly natural appearance. The mitral valve was probably competent; the aortic allowed regurgitation. The left ventricle was moderately hypertrophied and considerably dilated; the muscular tissue measured seven-eighths of an inch at the base and three-sixteenths of an inch at the apex; it was firm and dense, but through the somewhat thickened endocardium yellow fatty striæ were seen in the muscular tissue. Lungs: the trachea and bronchi contained frothy mucus; there was a caseous nodule at the apex of the left lung, surrounded by some fibrous changes; the lower lobe was partially collapsed, its tissue condensed and rather œdematous. The right lung was œdematous in the lower lobes, but crepitant. The liver weighed 62 ounces, had a nutmeg aspect on section, and was much indurated. The spleen weighed ten ounces and three-quarters, was firmly adherent to the under surface of the diaphragm, which had been fixed in the position of expiration by the pleuritic changes. In the spleen there were three old cicatrices along the anterior margin, remains of old infarctions. All were in process of contraction, their caseous contents dwindling, one surrounded by a zone of congestion. On the posterior surface of the right kidney there was a large puckered cicatricial-looking patch, where the renal tissue had been completely destroyed by an infarction, which had undergone absorption; the cortex was swollen. The cortex of the left kidney was much swollen, and of a pale buff tint, the surface studded with fine hæmorrhages."

The discovery of the miliary granulations in the least adherent portion of the pleural membrane proved the tubercular character of the pleurisy, a character which, had the thickening and adhesion been carried as far at the upper as it was at the lower part of the sac, might have been entirely missed; and the inference based on the clinical course of the case been incapable of proof. The case, then, gains much in interest in being an example of tubercular pleurisy with effusion; and the source of the tuberculosis lay in the caseous focus at the apex of the lung, a relic probably of the attack which befell him in boyhood. The case, then, does not bear out the statements of some writers that tuberclar pleurisy is invariably a *pleuritis sicca*, nor that of others that if there be effusion it is sanguinolent. I have had one other case of large serous pleurisy which proved to be tubercular, paracentesis being performed, and with much benefit, but without complete restoration. The patient died in an epileptoid seizure about two months after the tapping, and pleural as well as pulmonary tuberculosis was found.

The cardiac lesions were, as suspected, mainly upon the aortic valve, the cusp of which was so much disorganised that no question can be raised as to the murmurs described being generated at this orifice. The fact, noted more than once, that the diastolic bruit was better heard over the sternum and to the left of it than over the aortic cartilage is a common experience; but the sharp second sound that was audible at the latter spot must have been the pulmonary, for no second sound could possibly be produced by cusps like these. Whether the apex systolic bruit was really due to mitral regurgitation or not I cannot say. Certainly, the absence of any auricular dilatation shows that if the mitral valve were incompetent, it could only have been so for a very short period. The precise character of the aortic endocarditis in this case, and the manner in which the mitral cusp has become involved, are also points to be considered. The large mass of vegetations and the ragged condition of the aortic cusp, the vegetations spreading over the surface of the mitral valve and the ulceration that had taken place, show that the inflammation was still in progress, or, what is more likely, that it had been lighted up afresh; for the changes in spleen and kidney pointed to the occurrence of embolism at a date long prior to the present illness, and enable us to affirm the long duration of the aortic mischief, which the calcareous deposit in the valves also does. Far more recent, however, has been the ulcerative change on the one aortic cusp and on the mitral, which, destroying the ventricular part of the curtain at one or two spots, had led to the small aneurysmal patches which projected upwards from the valve into the auricle, and the perforation of one of which must have caused a minute current of blood to flow from one chamber to the other. (Did this suffice to produce the "mitral" bruit?) The exciting cause of this spreading inflammation on the mitral valve was in all probability the friction of the long, semi-calcified mass of aortic vegetations, as these swayed back with the regurgitant eddy through the aortic orifice. The fatty degeneration of the ventricular wall, together with the aortic disease, sufficiently explain the sudden death.

I have ventured to bring forward this case—1st, because of the occurrence of a large pleuritic effusion in cardiac disease; 2ndly, because of the tubercular nature of the pleurisy; and 3rdly, because of the character of the endocarditis. How far the lowered state of health of the man may have aided in rekindling the endocardial inflammation, and that a link may in this way be established between the two conditions, is an open question. Otherwise it seems to me that we have here in one subject an unusual combination of two uncommon conditions, each of which is by itself a necessarily fatal disorder.

OBSTRUCTION OF THE ŒSOPHAGUS TREATED BY GASTROSTOMY.

BY CHARLES N. MACNAMARA, F.R.C.S. ENG.

J. E——, a tailoress, aged fifty-one, married, was admitted into the Westminster Hospital on May 5th, 1884, under the care of Dr. Donkin. She stated that she had been quite unable to swallow anything for the previous three weeks; that she had constant pain, though not severe, in the chest, and that she had lost much flesh. The patient had had no serious illness. She had been pregnant five times, with two miscarriages. Many years ago she had a rash on the skin and sore-throat, with considerable loss of hair. The family history was good, giving no evidence of hereditary disease. Thirteen months ago she first noticed some difficulty in swallowing solid food, and about six months ago the difficulty seemed to become suddenly worse, so that it cost much effort and pain to swallow anything solid, and vomiting followed in about ten minutes after doing so. The dysphagia increasing, all attempts at taking solid food were relinquished, and only liquids were taken. Three weeks ago, however, even liquids were returned almost immediately. She was then admitted into a hospital where she had been attending for six months as an out-patient, and was fed with nutrient enemata.

On admission into Westminster Hospital the patient was seen to be extremely emaciated, with a somewhat sallow skin. She complained of pain behind the lower part of the sternum, and of great thirst; there was some tenderness on deep pressure over the supra-sternal notch. No tumour could be felt in the neck, or in any part of the body. The heart sounds were clear, but weak. There was no dyspnœa, nor any alteration of voice. The lung resonance was good. On deep inspiration the breath sounds were heard much less loudly over the right side of the back than over the left.

Digitized by Google

On examination the abdomen appeared to be normal; numerous hard masses were felt at first, but these disappeared after an enema. Œsophageal bougies were passed, but all stopped at a point about twelve or thirteen inches below the teeth; a small-sized one (No. 6) passed no further than a large one; the passage caused a little pain. About three hours afterwards she brought up some pultaceous material, undigested, without acid reaction. Nutrient enemata were given every three hours, and were well retained. Any liquid given by the mouth was at once returned.

On May 9th, with a view to probable gastrotomy, Mr. Macnamara was called in consultation. He failed to pass the smallest instrument through the obstruction, and, as some bloody mucus was attached to the end of the bougie on its withdrawal, he thought it undesirable to make any further attempts to reach the stomach, and strongly advised the operation of gastrostomy, as the patient was rapidly failing.

At 1.30 P.M on May 14th, the patient being anæsthetised, Mr. Macnamara commenced the operation. As carbolic spray had been employed in the room for two hours previous to the operation, and all the instruments &c. were soaked in carbolic solution, no other antiseptic precautions were taken. A curved incision, about three inches long, having its convexity towards the middle line, was made parallel to and on the inner border of the left costal cartilages, beginning about an inch and a half below the ensiform cartilage. After the bleeding had been arrested, the peritoneal cavity was opened by a cut as long as the skin incision. Portions of large intestine and omentum at once protruded and were returned, and Mr. Macnamara had to enlarge the incision upwards about three-fourths of an inch, exposing the left lobe of the liver. The anterior surface of the stomach was now seen under and to the left of the liver, and a fold of it was drawn through the wound by dressing forceps tipped with rubber. This fold of the anterior wall of the stomach was then transfixed by a needle loaded with stout silver wire; the needle was then passed through a piece of the skin on the thorax, and the wire was there twisted and fastened. The edges of the abdominal wound were then brought together round the protruding portion of the stomach by silk sutures passed through the whole thickness of the wall and peritoneum. At no point was the stomach stitched to the edges of the wound, but the wire suture held it in its place, the piece of stomach protruding through the walls of the abdomen being about the size of the half shell of a walnut. Mr. Macnamara then thought that the wire stitch might cut through and the stomach fall back into the abdomen; so he transfixed the protruding part with a harelip pin placed transversely, so that it rested on the abdominal wall on either side of the wound. Thus all traction was taken off the silver wire, which might then have been removed, but to make quite safe this was not done. The wound was dressed with vaseline spread on lint, two large Gamgee pads covering this. This form of dressing was continued until the patient recovered and all dressing was dispensed with.

On May 15th the patient complained of much pain in the stomach and intense thirst; tongue furred and dry. Pulse 64; temperature 98°. The wound was cleaned and dressed. Nutrient enemata were given every four hours, with twenty minims of tincture of opium in the last one at night; she slept fairly well. On the 17th the wire stitch was removed; the wound looked very healthy and was uniting well. Pulse 65; temperature 98°. The patient still complained of much pain in the abdomen, which was tender; no tympanites. A simple enema was ordered, which acted copiously and gave much relief. At 1 P.M. on the 21st, the seventh day after the operation, Mr. Macnamara made a small opening in the protruding portion of the stomach with a Graefe's cataract knife; the incision was only just large enough to allow the introduction of a No. 8 gum and silk catheter. Through this were injected one ounce and a half of beef-tea and a teaspoonful of brandy. At 6.45 P.M. four ounces of beef-tea and three drachms of brandy were injected; the patient then said she felt full and satisfied. Temperature normal. On the 22nd the patient looked rather jaundiced; urine high coloured. A simple enema was ordered, and this relieved her discomfort. On the 22nd four injections of four ounces each and four of nutrient enemata were given alternately, and this plan of feeding was adhered to for six days. Temperature normal. The enemata were gradually discontinued, and the patient tried to swallow a little fluid by the mouth to relieve her great thirst, but was unable to do so. On the 29th she had her last nutrient enema of milk and egg. She could now swallow a very small quantity slowly.

The harelip pin was withdrawn a fortnight after the first operation, and the stomach receded considerably during the next few days, till it was below the level of the abdominal wall. The food administered by the stomach consisted of milk and egg, beef-tea, Carnrick's peptonoids, and arrowroot; these generally in succession every four hours, about four ounces at a time. If more were given at a time, the patient complained of feeling overfull and uncomfortable. Benger's liquor pepticus was mixed with the food during the first fortnight. The temperature never rose above normal, nor the pulse over 70°.

From June 14th the patient rose at 11 o'clock every morning and sat up all day, dressed in her ordinary clothes.—21st: Up to this time the patient had, since May 22nd, been able to swallow a little fluid, but no solid food. She was now, however, totally unable to take food by the mouth; if she attempted to swallow the fluid caused pain, and was almost immediately returned. The patient was up and about; she had gained flesh, and had no trouble whatever in injecting food into the stomach through the opening in the abdominal walls.

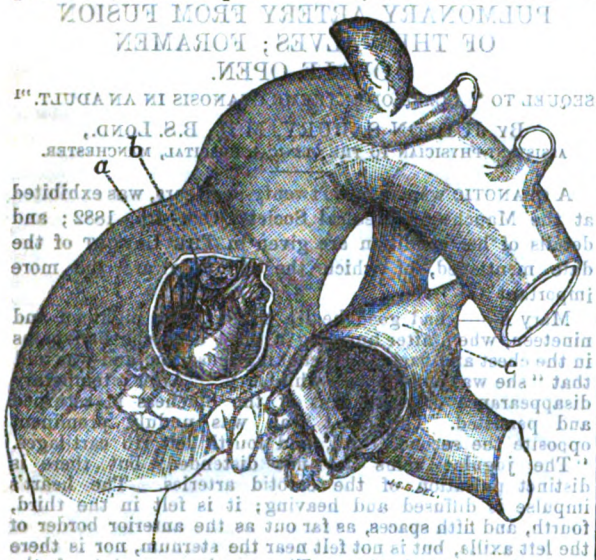
The above details from the date of the operation have been drawn up by Mr. Herbert Pulling, house-surgeon at Westminster Hospital, to whose great care and judgment the satisfactory termination of the case is largely due.

CONGENITAL CONTRACTION OF ORIFICE OF PULMONARY ARTERY FROM FUSION OF THE VALVES; FORAMEN OVALE OPEN.

SEQUEL TO "A CASE OF EXTREME CYANOSIS IN AN ADULT."[1]

BY JUDSON S. BURY, M.D., B.S. LOND.,
ASSISTANT-PHYSICIAN TO THE CLINICAL HOSPITAL, MANCHESTER.

A CYANOTIC woman, aged twenty-one years, was exhibited at the Manchester Medical Society, Oct. 4th, 1882; and details of her condition are given in THE LANCET of the date mentioned, of which the following are the more important:—



Mary F—— had good health till between eighteen and nineteen, when, after hurrying a good deal, she had pains in the chest and back and a choking sensation, and was told that "she was as blue as a whinberry." After a temporary disappearance or abatement of the blueness it returned and persisted. The chest wall was unduly prominent opposite the second, third, and fourth left rib cartilages. "The jugular veins are not distended, but there is distinct pulsation of the carotid arteries. The heart's impulse is diffused and heaving; it is felt in the third, fourth, and fifth spaces, as far out as the anterior border of the left axilla, but is not felt near the sternum, nor is there any epigastric pulsation. The maximum point of the impulse is in the fifth space in the nipple line; no thrill. The cardiac dulness is much increased, and laterally rather than vertically, extending from about one inch to the right of the sternum to almost the middle of the left axilla; the third rib marks the upper limit of superficial dulness, though the first two spaces are higher pitched than those on the right side; the sixth rib is the lower limit. On auscultation a high-pitched, systolic, whistling murmur is heard at the base, of maximum intensity over the first piece of the sternum; it is well conducted down this bone, being also well heard at the right sterno-clavicular articulation, and faintly in the carotids. A vertical line from the middle of the left clavicle marks its extreme left limit, and the murmur is gradually lost as the stethoscope is moved towards the apex; it is not heard behind; the sounds at the left apex are quite pure. The second sound is accentuated over the pulmonary cartilage, and is louder than at the aortic cartilage. The pulse is regular in rhythm, but not quite regular in force; it is equal on the two sides, and is felt in the femorals and in other arteries."

The patient was seen again in February, 1883, when she stated that she had had attacks of fainting for about a month, and that the pain in her chest was worse; it was noted that the cyanosis had increased, and that the systolic basic murmur was not so loud as formerly, but the heart in other respects was unaltered. The chest pains and difficulty in breath-

[1] Reported in THE LANCET, 1882, vol. ii., p. 801.

Digitized by Google

ing became more severe, and early in April she was admitted into the hospital. On April 5th, at 1 A.M., the house-surgeon, Mr. Buchan, was called to her: "she was insensible, breathing stertorously, the pulse was rapid and very thready; there was no rigidity or spasm of muscles. Mustard poultices were applied to the cardiac region and an enema of brandy administered. The patient remained unconscious for half an hour and then slowly recovered, answered questions, but was very drowsy and heavy for some time. Temperature 100·8°. Later on in the day she seemed much as usual, and did not complain of anything." On April 23rd my colleague, Dr. Railton, carefully examined the heart and made the following note: "The basic systolic murmur is faint, it is heard equally in both the aortic and the pulmonary areas; no accentuation of the pulmonary second sound is perceptible. The murmur is continued down the sternum, but another murmur, systolic in time and of greater intensity, is heard at the base of the ensiform cartilage. There is no venous pulsation in the neck, and no perceptible pulsation of the liver, but the liver is very tender to pressure. The right auricle is largely distended, as testified by the absolute dulness to the right of the sternum as high as the third rib." On April 30th the patient complained of severe headache, especially at the back. On May 1st, at 12.20 A.M., Mr. Buchan found her screaming with pain in the chest, the cyanosis was excessive, the pulse 130 and very thready, her breathing became stertorous and she quickly passed into a state of profound coma, and died at 1 A.M.

At the necropsy, made fifteen hours after death, rigor mortis was well marked. The length of the body was about fifty-six inches, the limbs were well formed and the subcutaneous fat was everywhere abundant. The lips, ends of fingers, and toes were of a dark-purple colour. On removing the sternum and costal cartilages the pericardium came prominently into view, the tip of the lower lobe of the right lung was also seen, but the left lung was out of sight, being shrunk and bound down by firm fibrous bands. Transversely the exposed pericardium measured six inches and a half, and vertically in the mid-sternal line nearly four inches. The liver was much enlarged, had its lower margin in the same line four inches and a half below the pericardium. On opening the latter the heart, of large size, was placed with its longest diameter transversely, it was also tilted; its anterior surface was made up of right auricle and ventricle, the left ventricle being out of sight. The outer margin of the right auricle was two inches to the right of the right edge of the sternum; both the right cavities were distended with black blood. The heart, separated and emptied weighed seventeen ounces, just double the average weight in females at this age; it was square in shape and measured five inches from the root of the pulmonary artery to the apex, and four inches and a half from side to side. The four pulmonary veins were traced to the left auricle. The pulmonary artery after dividing normally into two branches appeared to be prolonged by means of the ductus arteriosus into the aorta; but subsequent dissection showed that there was no opening into the latter, but that the lower part of the duct consisted of a conically shaped space (see figure, *c*), the closed apex being three millimetres or one-ninth of an inch from the aorta. The valves of the pulmonary artery were blended, and formed a thick dome-shaped projection into the root of the artery, dividing the space at its base into three deep pockets. At the top of the dome was a slit-like aperture (*a*), one-eighth of an inch in length, and admitting easily the end of an ordinary probe; it was lined by minute vegetations, and on the wall of the artery immediately above and on the aortic side of this aperture was a small raised cluster of vegetations (*b*). The opening mentioned formed the only direct communication between the right ventricle and the pulmonary artery; the latter and its branches were smaller, and had thinner walls than normal. The right auricle and ventricle were dilated and hypertrophied, the muscular substance of the ventricle being dark-red and unusually firm and thick, and the musculi papillares very large. The tricuspid orifice admitted the tips of two fingers; granulations covered with fibrin were found on two of the segments of the valve: namely, on the left one—that resting on the ventricular septum—and on the anterior one, in each case on the auricular surface and near the lower edge, the crop of vegetations on the anterior cusp being much the larger and a quarter of an inch in diameter. The coronary sinus appeared much larger than natural; its auricular end was nearly half an inch in diameter. The foramen ovale, widely open, measured seven-eighths of an inch vertically and five-eighths across, a portion of the valve with a sharp edge projected from the posterior and lower side of the foramen. The left were, as compared with the right cavities, small in capacity; the ventricular wall was thickened, and its maximum thickness was a little greater than that of the wall of the right ventricle (for measurements see below). The left auriculo-ventricular opening was not quite so wide as the right one, scarcely admitting the tips of two fingers; both segments of the mitral valve were thickened just above their free edges, but there were no signs of recent endocarditis. The aortic valve presented slight irregularities; the two posterior flaps were firmly united for a short distance from their common angle of origin; they were also fenestrated near their junction with one another and with the anterior flap, at each corner of each of these valves were two small holes crossed by a slender fibrous band; the lunulæ of the anterior cusp were entire. Above the valve small patches of atheroma were present on the wall of the artery. Both the aorta and pulmonary artery were unusually small, alike as regards their calibre and the thickness of their walls; the aorta looked slightly constricted after giving off the left subclavian, and the lumen here was half an inch less than at the origin of the aorta. There were two instead of three primary branches, the left carotid and innominate starting as a common trunk. The accompanying table of measurements brings out, amongst other things, the contrast between the size of the heart and that of its orifices and the two arterial trunks; the former is larger, and its walls much thicker, the latter smaller and thinner, than natural.

*Dimensions of the heart, in inches.**

The lungs, much congested, were free from tubercle. The kidneys, spleen, liver, and brain were also very congested, and, as seen in the table, heavier than natural. Slices of the brain exhibited black bleeding points. The liver, large and firm, presented the characteristic nutmeg appearance, and showed under the microscope great dilatation of the veins, especially of the intralobular ones, and around the latter the liver cells were much wasted, the intervening spaces being filled up with yellowish-brown pigment granules. There was also a small-celled infiltration of the periportal connective tissue. The kidneys were firmer than natural, and sections showed a commencing interstitial cirrhosis, and all the bloodvessels and large tracts of tubules were filled and distended with red blood-corpuscles.

Remarks.—The view taken of the case during life—namely, "that the origin of the pulmonary artery was affected with endocarditis in fœtal life; that the effects of its obstruction were compensated for by the persistence of communication between the two sides of the heart, and perhaps also by a patent ductus arteriosus"—is shown by the post-mortem examination to have been in the main correct. But now, further, we see, from the absence of any defect in the septum between the ventricles, that in all probability the pulmonary artery became diseased late in fœtal life, after the completion of the septum, and that at birth the contracted orifice rendered the artery incapable of transmitting the increased current of blood to the lungs, and then the ensuing strain on the right ventricle would keep open and be relieved by the foramen ovale. With so much obstruction at the exit of the right ventricle the relatively large size of the pulmonary artery and its branches appears somewhat remarkable, and one would expect to find a patent ductus arteriosus or some other channel by means of which blood could enter the artery. But perhaps the narrowing of the pulmonic aperture from blending of the similunar cusps was slow enough to permit the closure of the duct, and attained its maximum some time after this closure; and even with a small communication between the ventricle and artery, the latter would be kept full of blood, and so maintain a fair size or dwindle very slowly. In the previous report it was pointed out that many of the physical signs suggested obstructive disease at the aortic orifice, thus the systolic murmur loudest at the top of the sternum was traceable towards the inner end of the right clavicle, and along the carotids; there was no epigastric pulsation, but a heaving impulse in the left mammary region. The autopsy revealed excessive hypertrophy with some dilatation of the right ventricle, and moderate hypertrophy of the left ventricle associated with a partial fusing of two cusps of the aortic valve; the frenum thus formed projecting into the aortic aperture would be likely to evolve sonorous vibrations in the blood of the ascending arch, and at least may be offered as an explanation of the fact that a systolic bruit was heard as well below the right as below the left clavicle, in the latter position generated with greater certainty by the narrowed pulmonic orifice. In the presence of such extreme right hypertrophy the absence of any perceptible transmitted impulse to the lower end of the sternum or to the epigastrium, is a striking clinical feature, and one to be remembered in making a diagnosis of unusual heart conditions. The chest was repeatedly examined, and yet no pulsation was ever felt near the sternum, and the maximum point of the heaving impulse was always about the left nipple-line. These signs receive some interpretation by a consideration of the rotated transverse position of the heart with its concealed hypertrophied left ventricle. The fenestration of the aortic valve is probably a congenital defect, and would not give rise to much, if any, regurgitation. The small size of the arch is noteworthy, and especially the constriction of the third portion. During the last few weeks of life a systolic murmur was heard at the ensiform cartilage, and the pulmonary second sound became weaker. The fibrinous deposits on the tricuspid valve and the resulting imperfect adaptation of its segments give reasons for a tricuspid murmur; and it has been said that tricuspid regurgitation will lessen the intensity of the second sound at the pulmonary cartilage.[2] Probably at this time, too, endocarditis was lit up in the pulmonary artery. Such gradually increasing obstacles to an already overstrained heart fully account for the increasing distress, the final paroxysms of pain, the quickly ensuing comatose death, and for the intense venous congestion of the brain and other organs found after death.

Many similar cases to the one related are to be found in medical literature. Thus, Dr. Peacock[3] collected notes of twenty persons who presented this anomaly—namely, obstruction at the orifice of the pulmonary artery with an open foramen ovale, and eleven of these lived to the age of fifteen years and upwards.

JEQUIRITY (ABRUS PRECATORIUS, LINNÉ); ITS USE IN DISEASES OF THE SKIN.

BY JOHN V. SHOEMAKER, A.M., M.D.,

LECTURER ON DERMATOLOGY AT JEFFERSON MEDICAL COLLEGE, AND INSTRUCTOR THEREON IN THE POST GRADUATE COURSE OF THAT INSTITUTION; PHYSICIAN TO THE PHILADELPHIA HOSPITAL FOR DISEASES OF THE SKIN, ETC.

ALTHOUGH a drug of great antiquity, centuries ago in use in Egypt, and well known in Sanscrit by the name of Gunja to the Hindoos and Burmese, jequirity again comes forward as a most formidable weapon in the hands of the physician in his battle with disease. Prosper Albinus in 1592 quotes it as in use in Egypt. The resemblance of the plant to liquorice was remarked in 1700 by Sloane, who called it Phaseolus glycyrrhites. It was introduced in the Bengal Pharmacopœia in 1844, and in that of India in 1868. Its names and synonyms are so numerous as to cause me to omit the majority of them, which are claimed to number over fifty. It is frequently called Brazilian peas, Indian liquorice, wild liquorice, with equivalent terms in other languages, but by the rules for our terminology it should be known as "abrus." The seeds are now almost exclusively employed, and will only be considered hereafter in speaking of it. The plant belongs to the natural order of Leguminosæ. It is indigenous to India, but grows wild in all tropical countries, and though found in the primeval forests of Brazil, whence our supply is now mostly obtained, it is claimed to have been brought there by birds, or otherwise. The seeds, also called prayer beads, jumble beads, crabs' eyes, &c., are globular-ovate, about one-fifth of an inch in length, scarlet-red, glossy, with a black spot surrounding the hilum. The testa is hard, enclosing a fleshy embryo of plano-convex cotyledons, and accumbent radicle. They are inodorous and have a bean-like taste. Their chemical composition has been frequently investigated. Berzelius in 1827 found in the leaves and branches a principle resembling glycyrrhizin, also present in the root, which contains sugar, though he mentioned nothing of other constituents. Prof. Harden, in 1882, by treating the seeds with boiling alcohol, obtained white crystalline abric acid, slightly soluble in cold water, and said to have the formula of $C_5H_{14}NO$. They also contain fixed oil. Rigaud and Dusart in 1883 isolated from them an alkaloid, but neither the acid nor the alkaloid appears to be their active or toxic principle.[1] Mello E. Oliveiro, on treating the seeds with boiling water, slightly acidulated with hydrochloric acid, separated a bright-rose-coloured substance, which, on the addition of 45 per cent. of alcohol, changes to red, a greyish-white substance of a gummy nature being deposited. The red liquid thus obtained after exposure to light, assumes a greenish colour, persisting for some time. Dr. Neisser believes its active principle to be, so far, not yet isolated amorphous ferment, which Salmonsen and Dorkirk Holmfeld claim as insoluble in alcohol, chloroform, benzine, and ether, but slightly soluble in water and very soluble in glycerine. They claim to have obtained it by treating the powdered seed with ten times its weight of glycerine, from which it was precipitated by five times its volume of alcohol. The microscopic inspection of the fresh infusion by Dr. Silva E. Chanjo developed the presence of polyhedric cells filled with granular protoplasm, which he considers cells of the seeds, separated in the bruising and macerating; also round spherical very brilliant bodies, capable of movement either around their axes or in a forward direction, which with a lower power looked like a fine powder. The older infusion exhibits, besides the powder which

Digitized by Google

he considers as conidia, true cells and tubes of a microscopic plant with spores and mycelium. The spores he states as large, ovoid, sometimes solitary, or in groups of two, three, or more. The tubes either bear spores or are bare, and are branched, and between them the powder mentioned as conidia is seen. These are stated to be the more marked the older the infusion. Sattler of Erlangen states that schizomycetes, or cleft fungus, exists in the infusion in immense numbers. These he classes with bacilli. These microbes are found in the infusion five minutes after it is made, using warm water for that purpose. He claims that they increase by a sort of segmentation, giving off spores when about forty-eight hours old. Their property of vegetating is retained on remoistening after drying for a week, while in an ice-chest their development is arrested, and a temperature of 180° F. for five minutes does not affect the germinating power; but the infusion is entirely freed from germs by boiling, and was sterilised by a solution of mercuric bi chloride (1 in 10,000). The seeds have been often described as possessing poisonous properties, Herman even stating that two or three constitute a fatal dose. That this is not so would appear from the fact that though hard and indigestible, they have been used as food in Egypt and elsewhere. By Hindoo medical writers they have been variously recommended as an application in sciatica, stiffness of shoulder-joint, paralysis, and other affections. They are even said, when eaten, to prevent fecundity. The principal use of jequirity, however, is in certain affections of the eyes, for which it seems to have first found application in some parts of Brazil, where eye diseases are both frequent and virulent. The prevalent inflammations there are, if neglected, apt to develop granulations, followed by serious consequences. These granulations especially are one of the forms of ophthalmia which have proved so obstinate to treatment, and it is for this condition that jequirity seems to have been especially employed there empirically. Dr. Castro E. Silva published a paper on jequirity in affections of the eye in 1867, in which he calls attention to the dangers connected with its use. He speaks of cases in which after two or three applications a very intense inflammation of the eyelids and conjunctiva ensued, extending over the whole face, the neck, the upper part of the thorax, and even involving the submaxillary glands. A cold infusion is generally employed, which is applied to the eyes three times daily, so that some of it may pass under the lids. Even after the first application the eyes begin to "water," they feel burning hot, and the eyelids are heavy. The day following the inflammation is still more intense, the patient can no longer open the eyes, the lids swell, and are shining violet, ecchymosis of the conjunctiva is very marked, while an abundant muco-purulent discharge develops and the patient suffers great pain.

Dr. Moura, Brazil, made extended experiments on animals, especially rabbits; and in the strength of 1 in 20 produced a most intense inflammation of their eyes, which did not yield to any remedy, progressing to suppuration of the eyeball, gangrene of the lids, and inflammation of the submaxillary glands. The strength subsequently employed by Dr. Moura was 1 in 200, in the form of cold infusion, with which he produced, when applied to granular ophthalmia once a day, a moderate inflammation, and healing of the granulations in a few days.

Dr. L. de Wecker, of Paris, who, simultaneously with Dr. Moura, made observations on the action of jequirity in certain eye affections, gives his *résumé*, which is as follows: 1. There is no doubt that an infusion of jequirity produces a purulent ophthalmia of a croupous nature, the intensity of which can be regulated by the strength and number of applications. 2. The cornea runs no risk during the development of jequiritic ophthalmia. 3. The jequiritic ophthalmia cures granulations rapidly.

Dr. Knapp, of New York, regards the use of jequirity by no means without danger, and even holds that the secretion of the jequirity ophthalmia may be conveyed to and infect a healthy eye, and in a case where he tried it side by side with other means, he saw no particular advantage; and while he admits that it is a remedy in trachoma, it is not *the* remedy.

The latest report on the therapeutic value of jequirity in affections of the eye is probably that made by Dr. Arthur Benson before the Ophthalmological Society of the United Kingdom on March 13th, in which he sums up his results as follows:—Jequiritic ophthalmia can be produced (1) by the powdered seed; (2) by the freshly made infusion; (3) by the infusion after bacilli had grown in it; (4) by the infusion six weeks old, and swarming with micro-organisms of most varied types; and (5) by the infusion after these bacilli had ceased all motion, and had sunk apparently dead. The examination of the discharges from jequiritic ophthalmia revealed no typical bacilli, and were entirely devoid of infective qualities. He had a high opinion of the treatment of granular lids with jequirity, and had seen no serious results therefrom.

After considering all the foregoing observations, it certainly occurred to me that jequirity possesses qualities which make it act as a destructive agent upon the granular tissue of the eyelids, causing an inflammatory process which has all the characteristics of that produced by an escharotic, without the effect that the general class of the latter produces upon the surrounding tissue. If we consider by what means this is accomplished, we must certainly exclude chemical action of any kind, as the proximate components of the seeds have been shown to be innocent in their action on the animal organism. That they are even consumed as food would warrant us further in assuming them as such, else most certainly gastro-intestinal irritation of the most violent kind would be produced by them. That they need a third element to develop their destructive effect upon organic structure seems therefore evident. This can be construed as arising from two sources only. One of these would be explained by the development of a new substance formed by the action of the moisture on a certain ferment and bodies capable of being acted upon by it, as is the case in the emulsion and amygdalin of bitter almonds and the sinigrin and myrosin of mustard; but physical evidence for such a change in jequirity is wanting, as it betrays neither by smell nor taste the presence of a new product. The experiments and results of Neisser, as well as those of Salomonsen and Dorkirk Holmfeld, would warrant the assumption of this, and if their amorphous ferment obtained by glycerine extractions and alcohol precipitation really produced in solution the specific jequirity ophthalmia, the inference would lead us to such a theory. Possibly sterilisation, however, of jequirity infusion by mercuric bichloride and other antiseptics, as well as by boiling, renders this most untenable and improbable. There is evidently another agency concerned in this most remarkable action of jequirity, more so than the development of a new chemical irritant in that body. This we must look for in the atmosphere which we have been taught by Pasteur and others to regard as bearing the germs of more micro-organic development in soil suitable and chemically composed for their sustenance. This seems a more likely and plausible view from the fact that a proteid body and solution of its albuminous parts in a cold infusion is rapidly invaded by new growths of micro-vegetation possessed, as described above, both of conidia and mycelia. That it thus forms a nutrient liquid for the cultivation of germs there seems no further doubt, and that these can be destroyed and further growth arrested by either boiling or mercuric bichloride has been experimentally proved. That during the development of the new growth no carbonic acid gas is developed or acid formed shows, further, that the microbe owes its development not to an oxidation or destruction of any hydrocarbon contained in the bean. My deduction, therefore, leads me to the conclusion that the fungoid growth of the infusion, originating from bacterial influence of the atmosphere, must proliferate at the expense of the albuminous contents of the infusion, which in its rapid proliferation it destroys unto its own ultimate death. My argument is intended to show further its relation to cellular tissue and cell contents, in order to explain the *rationale* of its destruction of granular tissue. The bacterium applied to such cell structure finds in these and their contents all the elements necessary to its own growth and reproduction, casting the effete product on the surface, until by exclusion of atmospheric air and over-production its own existence ceases. That it is a typical disease carrier which could be employed to wage war and exterminate hostile micrococci is certainly ridiculous in the extreme, as well as that, like the ubiquitous bacillus, it acts on the vaccination principle by rendering the organism no longer a fertile soil for the invasion of other micro-organisms. The inference from this deduction led me to experiment with jequirity on a larger sphere and in affections which present similar pathological conditions, as the granular lid. As the action of the fungus developed in the jequirity infusion seems to destruc-

Digitized by Google

tively attack the proliferating cell, while it does not act in such a manner on the external coverings and mucous surfaces, I employed it to affections of the skin showing great cell proliferation; as such I selected lupoid conditions, epitheliomæ, sloughing ulcers, &c. When at first disappointed with the ordinary infusion used in eye affections, and also with the dry powder dusted over the surface, I applied to Dr. L. Wolff, the well-known chemist, for a more effective preparation, which would not alone be much stronger, but which would at the same time be more viscid, so as to adhere longer to the surface. This he accomplished in a most successful manner in the following way:—Two hundred grains of the bean are decorticated by being slightly bruised and cracked in a mortar, the red hulls are carefully picked from the cotyledons and, in a bottle, covered with distilled water. They are thus macerated for twenty-four hours, when they are again transferred to a mortar and thoroughly triturated, until they are reduced to a smooth paste, when sufficient water is added to make the whole weigh 800 grains. Prepared in this way it presents all the appearances of an emulsion, and is applied with a large camel-hair pencil or mop to the surface to be treated. The effect of this preparation of jequirity, while almost painless in its application to ulcerated and granular surfaces, soon developed (and often within an hour) a great deal of irritation and inflammation, rendering the edges red and infiltrated, the surroundings œdematous and shining, and caused some febrile exacerbation in the patient, depending in degree on the area involved. The usual concomitant symptoms of such febrile process are apt to show themselves at this stage, such as headache, pain in the extremities, elevated temperature, and high pulse, all of which, however, are not general, but found only occasionally, and particularly in irritable and very susceptible patients. In the course of from six to twelve hours, the products of this specific inflammation are abundant, and soon aggregated on the surface in a desiccated, cuirass-like crust, which now obscures further observation. This crust, in the course of twenty-four hours, further exhibits a tendency to crack and break, giving vent to the flow of the products of the degenerative process. This condition, if left alone, will continue for five to six days, the discharge lessening by degrees, the firmly adhering crusts, if not detached on their own account, are now removed by water dressings, and expose to view a surface studded with healthy granulations and islets of healed-up surface, along with evidence of the progress of the regenerative progress at the periphery. In cases where one application does not suffice, and where there is still evidence of the presence of unhealthy granulations, a second application is now made, and conducted as before, and a third and further application being made, as the case may require.

The results thus obtained with jequirity will best be seen from the citation of a few cases from the case book of the Philadelphia Hospital for Skin Diseases.

CASE 1.—John T——, aged thirty-five years, car conductor, has been under treatment for some time. Specific ulceration on the right leg. He cannot give up his occupation. Under specific treatment the colour of the edges improved, but showed no tendency to heal. By an application of jequirity in one week the ulcer was greatly improved, with edges smooth and healing; another application of jequirity healed up the ulcer completely after the second week.

CASE 2.—Jane W——, aged seventeen, factory hand. Scrofulous indolent ulcer on neck, easily bleeding with unhealthy ground. She was put under constitutional anti-scrofulous treatment. After an application of jequirity the crusts were removed in a week, the patient being greatly improved in health. After two weeks' applications the ulceration was looking healthy, and healed under simple dressings.

CASE 3.—Mrs. G——, aged forty. Ulcerating lupus, extending over the bridge of the nose. A case of Dr. Albert Fricke, of this city, to whom I was called in consultation. The patient had been under the care of several physicians. Escharotics and scrapers had both been applied, but to no advantage. I suggested the use of jequirity. The first application of a clear infusion proved of no avail, running off without causing any marked irritation. The concentrated emulsio-infusion was applied with a camel-hair brush every third day, until a firm cuirass-like scab was formed. After this had become spontaneously detached, at the end of three weeks, the surface entirely healed over.

CASE 4.—Mr. W——, aged forty-three. A large epithelial ulceration on the dorsal surface of the left hand. He met some years ago with an injury to the hand. He had gradually increasing lancinating and excruciating pains and preceding ulceration, until it entirely covered the dorsal surface. He had been under various treatment, with only partial amelioration of the symptoms. Had been cauterised and scraped with no permanent advantage. The concentrated emulsio-infusion of jequirity was applied in the usual way. It soon developed all the signs of the specific inflammation, leaving immense scabs, which were from time to time detached, and followed by new applications, when ultimately the entire surface was completely cicatrised.

CASE 5.—Lavinia W——, aged forty-five, seamstress. Ulcerating lupus on both sides of the face, a most desperate case. She had been under treatment for years, consisting of periodical scraping and applications of caustics as well as the cautery, which in every instance were followed by exuberant granulations notwithstanding the most careful local and constitutional treatment. The surface was affected in irregular patches, extending to no less than two and a half by four inches on each side. As a *dernier ressort* and a last case for the jequirity treatment, the concentrated emulsio-infusion was applied freely over the patches. It was followed by an enormous amount of inflammation, accompanied by malaise, febrile exacerbation, the temperature rising to 103°, which lasted until the cuirass-like crusts had formed and commenced to dry up. After these were detached and the applications renewed the same constitutional disturbance took place, lessening, however, in the proportion as destruction decreased the affected surfaces. After the fifth application the crusts were allowed to detach themselves spontaneously, and with it a well-healed surface was apparent all over the patches, granulations, tubercles, and ulcerations having entirely disappeared.

A number of other cases from the hospital case book could be cited would space permit, and I would only refer to the alarming constitutional symptoms reported by Medical Director Albert L. Gihon, U.S.N., in a case treated by him at my suggestion. In that instance the temperature of the patient, an old man, rose to 103°, but the ultimate result has so far not been reported.

To sum up. The results of the treatment of diseases of the skin with jequirity lead me to pronounce it a most powerful agent, applicable to most all cases of unhealthy, ulcerating and granulating conditions, upon which it certainly exercises a destructive tendency, followed by a constructive change, and forming under the protective covers of the exudation it causes a rapid development of healthy tissue. Though under proper conditions and careful supervision it is a remedy of the greatest service, it should be applied with caution, as it may give rise to alarming symptoms—erysipelatous inflammation and, if used on weak and irritable patients, to great constitutional disturbances. These symptoms, however, will speedily subside with proper attention and on the drying of the crusts. That jequirity has in still larger field than simply that of ophthalmic practice will readily appear as a deduction from my experience. Though the *modus operandi* of its action as stated by me may be modified in the course of time, its curative results in the class of cases to which I have referred will be indisputable, and be more freely developed as it finds more general application and introduction.

THE RADICAL CURE OF UMBILICAL HERNIA.

By W. MITCHELL BOOCROFT,

HON. SURGEON TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

TRUE umbilical hernia is a disease of such frequent occurrence that cases are constantly coming under our notice as surgeons. It is a disease of infancy and childhood, being almost always congenital. When it occurs in adults we more frequently find it in women, especially those who have borne many children, or who are loaded with internal fat; and even in these adults I think that the disease commenced in childhood, but is unnoticed or does not develop itself until the abdominal muscles have been weakened and the umbilical aperture relaxed by the pressure of the gravid uterus. When the hernia is small and reducible we can generally effect all that is desired by an accurately fitting

Digitized by Google

truss, though I doubt if a permanent cure is ever established by this method. It is in those cases especially which have grown to an enormous size as years have passed on, where the hernia is irreducible, the patient frequently suffering from flatulent distension, there is constant fear of obstruction or strangulation, or even where the surface of the tumour is covered with ulcerations, either the result of neglect or a badly fitting belt, that the surgeon feels it incumbent upon himself to recommend a means of cure beyond the usual methods of rest in the recumbent posture, strict attention to diet, and a belt or pad, &c. That such a means of cure exists, and is accompanied with less danger than is usually supposed, I hope the following notes may prove.

Margaret C——, aged fourteen years, was admitted under my care into the Wigan Infirmary on March 14th, 1884, suffering from a large umbilical hernia, with ulcerations over the surface of the tumour. On examination I find the patient is decidedly hydrocephalic, and presents evidences of having suffered from rickets. Is only thirty-eight inches in height, fairly well nourished, not very intelligent, though can answer simple questions. The corneæ are dull, the result of chronic keratitis. Family history good, though the mother died during the patient's infancy from alcoholism, so the child was probably neglected. I learn from the relations that the umbilicus was injured at birth through the neglect of the midwife; but they first noticed a swelling in the situation of the present tumour six years ago, when the patient was about eight years old. Since then it has gone on increasing in size, and has become ulcerated. The ulcerations do not heal, and are extending. On examining the abdomen I discovered a large umbilical hernia, rather larger than a cocoa-nut, covering the surface of the abdomen from within two inches of the ensiform cartilage to a point about three inches above the symphysis pubis. The skin covering the tumour is moderately tense, and presents several ulcerations over the anterior surface. The ulcerations seem to involve almost the whole thickness of the true skin, and discharge very offensive pus. Upon trying taxis I find that I can reduce most of the hernia, but a portion remains behind, and is irreducible. I discover the umbilical aperture will admit three fingers easily; consequently, taking into consideration the probable space occupied by the neck of the irreducible portion of the hernia, it is about two inches in diameter. The tongue is furred, and she suffers from obstinate constipation. Temperature normal.

Taking all the circumstances of the case into consideration, the great inconvenience of the tumour, the inapplicability of a belt or pad, the liability to obstruction or strangulation, the fear lest the ulcerations should extend into the sac and eventually establish an incurable artificial anus, with the anxiety of the relatives, and their urgent request that something should, if possible, be done to cure the patient, I decided to perform an operation which has hitherto been looked upon by surgeons as hazardous in the extreme. In order to prepare my patient for the operation, I gave instructions that she should remain in bed, to have milk diet, and the ulcerated surfaces to be dusted with iodoform, and absorbent pads repeatedly changed to render the part as near as possible aseptic. On March 20th I performed the following operation under carbolic spray, and with all necessary antiseptic precautions. The patient being under the influence of chloroform, as much of the hernia was reduced by taxis as possible. Two elliptical incisions were made, about five inches in length, uniting above and below, over the anterior surface of the tumour, including all the ulcerations. It was then found that the anterior surface of the sac was adherent to the skin, and could not be separated; so the sac was opened and the skin between the incisions, together with and including that portion of the sac which was adherent, removed. I then discovered that the irreducible portion of the hernia consisted principally of omentum, which was adherent to one side of the neck and adjacent portion of the sac. This was carefully separated, and the whole returned into the abdominal cavity. Four stout copper wires were next passed separately from without inwards on one side of the umbilical aperture, about half an inch from the margin, then involving the neck of the sac on both sides, and from within outwards, through the other side of the aperture, the point of the needle being the whole time guarded by my left index-finger. When the four sutures had all been passed, each was tightly twisted, and the aperture completely occluded. The ends of the wire sutures were brought out of the centre of the incision, and a drainage-tube inserted, traversing the whole length of the wound and protruding at each end. The sides of the incision were then brought together, except where the deep sutures escaped, with superficial carbolised catgut sutures, and the whole dressed in the usual antiseptic way, with plenty of crumpled dry gauze to absorb any discharge. I may mention that during the operation we had the greatest possible difficulty in retaining the intestines within the abdominal cavity. I had taken the precaution to have the bowels freely opened the day before the operation. I now ordered the patient to have no food by the mouth, but a little ice to suck, to check any vomiting or straining; nutrient enemata of two ounces of milk every two hours; the thighs to be flexed on the abdomen by means of a pillow under the legs, in order to take any tension off the abdominal muscles. A hypodermic injection of morphia at night if necessary. Night temperature after the operation 97°.—21st: Morning temperature 100°. Slept fairly well; did not require the morphia. Pulse 90; no pain. Has retained all the enemata but two; no vomiting. Evening temperature 101·4°. —22nd: Morning temperature 99·4°. Slept well; milk enemata, alternated with one ounce of kreechyle, all retained. Wound dressed; looks well; no suppuration; little discharge, which has all been absorbed by the crumpled gauze. Evening temperature 100·4°.—23rd: Morning temperature 99°. Slept well; feels very comfortable; no pain; enemata retained; says she is hungry, but still sucks the ice. Evening temperature 99·4°. —24th: Morning temperature 98·8°. Sleeping well, but complains of hunger; dressed; wound united in several places by first intention; no suppuration and little discharge; drainage-tube removed. From this date the patient continued to improve, the morning and evening temperatures remaining normal. The wound was dressed every second or third day and continued healthy. On the 25th the bowels acted naturally. On the 28th she was allowed a little of Brand's essence of meat by the mouth, and the enemata were discontinued. On the 31st the wound was dressed. A little suppuration was noticed, but the pus was not offensive. Two or three superficial sutures which had not become absorbed were removed.

April 4th.—In addition to the Brand's essence to have two pints of milk per diem. Bowels acting naturally.—13th: Patient placed under chloroform. By slightly enlarging the superficial incision through which the ends of the deep sutures passed these were snipped and withdrawn.—16th: Carbolic spray discontinued, dressed with an antiseptic absorbent pad; wound nearly healed.—19th: Temperature went up to 102°, but on dressing I found about two drachms of pus burrowing under one edge of the wound; on this being released, the temperature next morning returned to normal, and continued so.

May 1st.—Wound almost healed; patient discharged cured, but to attend for a short time as an out-patient. I saw her again on May 20th, when the wound had healed; there was a good firm cicatrix; the umbilical aperture seemed firmly and completely occluded, and the relatives assured me that she was in better health than she had been for years.

I know that surgeons in the past have displayed considerable apathy in adopting any active operative interference about the umbilicus, probably from a well-grounded supposition that operations in this region were almost invariably fatal. With the daily experiences derived from such operations as ovariotomy &c., where the peritoneal cavity is opened and the advantages of Listerism, such apathy must vanish; yet I hope the preceding remarks will not convey the impression that I would advocate a similar method of treatment in all cases of irreducible umbilical hernia. On the contrary, I am of opinion that only a few cases occur where the surgeon would feel himself justified in performing this operation. Moreover, I am quite cognisant of the fact that the experience of one case, no matter how satisfactory the result, is insufficient to arrive at any definite conclusion; yet I feel convinced that similar cases do exist where this operation, or some slight modification to meet the exigencies of individual cases, might advantageously be adopted and life saved. If my notes add one link to prove not only the feasibility, but, with careful attention to details, the hope of ultimate recovery, I shall rest contented that my efforts have been amply rewarded.

THE Library of the Royal Medical and Chirurgical Society will be closed on Monday, August 11th, and reopened on Monday, September 15th.

CASES OF ACCIDENTAL POISONING.

BY EDGAR BECKIT TRUMAN, M.D., F.C.S.,
PUBLIC ANALYST TO THE BOROUGH OF NOTTINGHAM AND TO THE COUNTY OF NOTTS.

I. BY ARSENIC.

ON Dec. 5th, 1882, I gave evidence at an inquest held by Mr. A. Browne, deputy district coroner for Notts, at Stapleford, near Nottingham. On Nov. 19th, 1882, C. W—— obtained from a shop kept by Mrs. X—— a paper packet of what was believed to be magnesium carbonate. It was dispensed by Mrs. X—— out of a large bottle containing with the powder a leaden tablespoon as a measure. C. W—— and his wife each took a teaspoonful of the powder in milk, and shortly after suffered from vomiting and purging. The husband, after much pain and discomfort, recovered; but the wife died on the third day afterwards. A post-mortem was made, and the appearances of the viscera were those of death from an irritant poison. The case was referred to me, and on Nov. 25th I received four jars containing respectively the stomach, liver, duodenum, and rectum, a bottle with the contents of the stomach, a large wide-mouthed bottle half full of a white powder, and with a leaden spoon within, and a paper packet of a white powder. In the viscera and contents of the stomach I found arsenic. The white powder in the bottle gave off the usual reactions of arsenious acid and of magnesium carbonate. The relative quantities differed in different parts of the whole, four samples taken giving percentages of arsenious acid of 46, 55, 45, and 55, or an average of 50 per cent. A teaspoonful of the powder levelled up weighed twenty-one grains, so that in a teaspoonful there was about ten grains of arsenic. There was no other metal present. Lead from the spoon was blamed for the result at first. The powder in this paper was identical in character with that in the bottle. It seems that Mr. B—— had kept a shop in this neighbourhood, and obtained his drugs from a leading druggist in Nottingham, who in turn got his stock from London. This Mr. B—— had, however, given up his shop in July, 1881, and at that time sold Mrs. X—— several quantities of simple drugs, including a large bottle of magnesia. The bottle sold to Mrs. X—— was proved to be the same as that from which Mrs. X—— dispensed the powder to C. W——. It was a bottle known to the whole village in fact. Mr. B——'s nephew gave this in evidence, and the nephew's wife said that she had given of its contents frequently to her own baby, and it had never suffered any ill effects. She said she was sure that the bottle when sold was not so full as when produced at the inquest. The bottle was not labeled. The coroner said, in the course of his remarks, that he was afraid it would remain a mystery as to how the arsenic got into the powder, for according to Mrs. X——'s evidence, the contents of the bottle were just the same as when she bought the powder from Mr. B——. The jury returned a verdict that the deceased died from taking arsenic accidentally mixed with magnesia, but how such mixture took place there was no evidence to show.

II. BY STRYCHNIA.

On March 18th, 1884, I gave evidence at an inquest held by Dr. Housley, district coroner for Notts, at Warsop, near Mansfield. W. H—— had a daughter, the deceased, who was ten years old at the time of her death. She occasionally suffered from toothache. On January 4th—i.e., six weeks before the death, finding her in pain from toothache, he sent her to a druggist's shop in Warsop for some Epsom salts. Of this he gave her a teaspoonful in some hot water. She then went to bed; her father and his wife, the child's stepmother, shortly afterwards retired. About 10 o'clock (time of child going to bed not given) the child began to scream. Her father went to her, and she said, "Father, father, I am dying." She complained of pains in the legs, which were stiff and extended. He carried her about the room for twenty minutes, and then put her on the bed. At intervals she screamed and asked not to be put on the ground. When sitting on the bed she said, "It's coming on again." She made "funny faces," and he thought she was "going off her head." After half an hour she vomited and seemed better, and he did not think it necessary to send for a doctor. He gave her a little whisky and water, and occasionally after this there was twitching in the arms, body, and legs. In an hour she went to sleep. Next morning she seemed dull and drowsy. He did not think at the time that the salts were the cause of her symptoms. On February 16th the child again complained of the toothache, and her father gave her half a teaspoonful of the same salts in hot water. She went to lie down, and in a quarter of an hour cried out for him. He found her suffering in the same way as before. He sent for Mr. Stein of Warsop, who found the girl unconscious and almost pulseless, with the face quite pale and the lips livid. She went into a series of convulsions, which attacked the body, arms, and legs. She shortly after died. Mr. Stein made a post-mortem, and finding no appearance of death from natural causes, and indeed stating that the symptoms were those of strychnine poisoning, reserved the stomach for analysis. On February 20th I received the following articles: (1) A white jar, covered and sealed; (2) a powder in a blue paper; (3) a small bottle labelled "toothache tincture."

1. The jar contained a small human stomach, tied at both ends, weighing 13½ oz., with the contents, which latter weighed 8¼ oz. The mucous membrane was natural. The contents consisted of a brown thick fluid, with an acid reaction, and of some lumps of cooked flesh resembling ham and some fat and potato. I examined these contents for magnesium sulphate, finding both base and acid present. I then took half the stomach and half the contents, making an acid watery extract, which I exhausted with alcohol, the alcoholic extract dissolved in water being treated, by a well-known method, alternately with chloroform and ammonia and sulphuric acid. Finally I obtained from the half of the stomach and contents a pure white crystalline evaporate from alcoholic solution, weighing ·007 of a gramme—i.e., in grains, for the whole stomach, ·007 × 2 × 15 = ·21 grain. I tested this alkaloid in the usual way for strychnia. The solution in acetic acid was intensely bitter to the taste, gave a yellow precipitate with chromate of potassium, and the solid showed the violet reaction with manganese binoxide and sulphuric acid. Nitric acid did not redden the solid, showing absence of brucia. To show that this substance was altogether strychnia, and not a mixture with some other alkaloid, I made use of two methods, chemical and physiological. The colour, reaction, and bitterness to the taste I found most marked to ·00001 of a gramme, and the physiological test I used as follows. Frogs I found it impossible to get, and instead thereof made use of toads, just then spawning and easily obtained. I took male toads of equal size, and made two solutions, one of the crystalline evaporate and one of a pure strychnia from Morson's, of the same strength. Into toad A I injected by the hypodermic syringe ·005 gramme of the alkaloid from the stomach; into toad B ·005 gramme of pure strychnia. A had first marked tetanic spasm in eighteen minutes; B in twenty minutes. A died in six hours twenty-three minutes; B in six hours thirty-three minutes. A third toad I put unwounded into a vessel containing a grain of acetate of strychnia. He had no symptoms for twenty-seven hours and a half, but died of tetanus in forty-six hours and a half, showing how much longer the thickly tuberculated skin of the toad resists the entrance of a solution of strychnia than in the case of the frog. The dose, ·0001 grain, recommended to produce tetanus in the frog, by a solution in which it is placed unwounded, had not the least effect on the toad for seventy-two hours, when I removed it, and it showed no sign whatever of tetanus afterwards.

2. The blue paper packet contained a white crystalline powder, weighing 355 grains. This was what the father had given doses of to the child, and was supposed to be Epsom salts. There was no label, either of the substance or of the druggist's name. I analysed this substance for oxalic acid and for zinc, with a negative result. I obtained the usual evidence of magnesium and of sulphuric acid. I found and separated, by of course a much simpler proceeding than in No. 1, strychnia in the alkaloidal state, and amounting to 3 per cent. of the whole, but not uniformly distributed. A teaspoonful levelled up weighed 52½ grains; so that it would contain about one and a half grains of strychnia, and the half teaspoonful about three-fourths of a grain.

3. The "toothache tincture" contained no strychnia, and consisted of a solution of camphor in chloroform. It had been used by the child.

The stepmother deposed that her husband had three children, but none by her. On two occasions, by his desire, she bought strychnia for the purpose of poisoning rats (the father was a gamekeeper); but said that the

Digitized by Google

last quantity, after what was necessary, was thrown into the fire; whilst the father said he distinctly remembered throwing it into a stream. After some little pressure, the stepmother admitted that the child's life was insured. Two of the neighbours deposed that in January of this year each of them had bought Epsom salts at the druggist's where the deceased child had purchased some. In one case the witness gave her daughter, aged ten, as much as would lie on a shilling, and the girl suffered from aching and stiffness of the arms and legs and twitching. Witness threw away the remainder of her salts when she heard of the death of deceased. In the other case the witness had taken a teaspoonful of the salts herself, had twitchings of the arms and legs, but vomited and soon recovered. The druggist who sold the salts deposed that he had no strychnia in the solid state, and had never had it in stock. The bulk of Epsom salts from which he supplied deceased came from a wholesale druggist's in London. The coroner reviewed the evidence at some length, pointing out that the questions for the jury to consider were: Whether the deceased died from poisoning by strychnia; and, if so, how was it mixed with the salts? Was it mixed wilfully and intentionally? Were the salts contaminated by the father, the local, or the London, druggist? He thought that the wisest course would be to return an open verdict, leaving any future action to be taken by the police, if they obtained sufficient information. The jury's verdict was: "That deceased died from strychnia poisoning; but there was not sufficient evidence to show how the poison became mixed with the salts."

Remarks.—I have brought forward these two cases, not for their pathological or chemical aspects but on a medico-legal account. They are similar, inasmuch as it was impossible to trace how, when, and by whom the mixture of poison and medicine took place. It seems to me to offer a new and facile field for the poisoner of the future. If A buys a medicine of B and a poison of C, and mixes them, who is to say whether A did so or whether B did not sell the medicine adulterated with the poison? Of course the greater number of hands the substance bought passes through the greater the difficulty of finding out the person who mixed with it a poison. In the first case the powder which killed Mrs. W—— was bought of Mrs. X——, who bought it of Mr. B——, who bought it of a druggist in Nottingham, who would buy of some London house. In the second case the salts were bought of a local man who bought of a London house. It would have been better in the second case if the police had seized the bulk from which the salts were dispensed by the local druggist.

The cases also were similar in respect of the varying strength of samples taken from different parts of the whole; looking indeed as if the mixture were an accidental one. The verdict of the jury was in each case in almost identical words, to the effect that death was caused by the poisoned medicine, but that there was no evidence to show how the mixture had been effected. My own theory with regard to the first case is as follows. Mr. B—— had been in the habit of keeping a little arsenic for the purpose of sheep-washing; this fact he kept in the background as much as possible, and there was no arsenic or indeed any drug on his premises at the time of the inquest. He probably or possibly kept this arsenic in a paper without a label, and when the necessity for using it had passed by he would push it into a corner of a cupboard and forget all about it. When transferring some of his stock to Mrs. X——, he would turn out this white powder in a paper; not labeled, he would imagine it was an additional quantity of what it so much resembled—viz., the magnesium carbonate—and would put it into the bottle containing his stock of the same. When Mr. B——'s nephew's wife gave her baby some magnesia out of this bottle, it would be before the transfer to Mrs. X—— took place. As to her saying that the bottle was fuller when produced at the inquest than when sold to Mrs. X——, that was possibly due to her imagination. The second case presents much more difficulty. The husband and wife, when examined separately, differed as to the mode in which the residual strychnia was disposed of, and it may perhaps be considered singular that the father, having poisoned rats so frequently, and most likely seen them in the convulsive stage, should have had no suspicion of the real state of things after the first dose. As to the whole teaspoonful being recovered from and the half proving fatal, in the first place the vomiting in the first instance would diminish the amount of poison absorbed, and, in the second place, too great reliance cannot be placed on loose measurements; the whole teaspoonful may have been a small one, and the half a large one. If the packet bought were really a two-ounce one, there must have been, after the teaspoonful and a half had been taken, an ounce unaccounted for; but as 355 grains (sent to me) + 50 + 25 (a teaspoonful and a half) = 430, the packet may have been an ounce only. As to the depositions of the two neighbours that they had suffered from twitching after taking salts purchased from the same druggist, we may perhaps attribute this, in the absence of any but their own testimony, to vivid imaginations acting posteriorly to the fact of the girl's death. I was told that two samples of salts bought from the same druggist had been sent for analysis to a chemist, and with negative results, but this was not put in evidence.

Nottingham.

"PRICKLY HEAT."

BY HENRY T. WHARTON, M.A. OXON.,
HONORARY SURGEON TO THE KILBURN DISPENSARY, ETC.

THIS distressing affection, so common among Europeans in tropical climates, is too rarely met with in England to figure in our text-books under anything but its mere name of "lichen tropicus." The apparent impossibility of relieving the fearful burning heat or the tormenting prickly itching seems to excuse dermatologists from even suggesting a remedy. Nevertheless the disease, although seldom recognised, is far from being unknown in this country. A well-marked case which has come under my observation, and which has ended in a complete cure, seems therefore worthy of being recorded.

My patient, a medical man, after passing the age of thirty suffered year by year continually increasing distress as each summer came round. He is a man of exceptionally good health, who knows nothing of indigestion, biliousness, or liver complaint in his own individual experience. At last his "prickly heat" became intolerable. Not only was the follicular lichenous inflammation so conspicuous on his back that he could not bear to take a Turkish bath in public; but the eruption would appear in considerable patches on his forearms, so that he was ashamed to turn up his shirt-sleeves in ever so troublesome an obstetric case. The disfigurement was almost as serious a matter as the pain. Yet, after having been out at night he would often return to his bed to suffer hours of the torture of his "prickles;" the least increase in the action of the skin brought them on; nor did any treatment prove adequate to bring the slightest relief. From May to November he was a martyr to his troublesome malady. He consulted all his friends and more than one distinguished specialist. His efforts to get cured were as unremitting as they were unavailing; no known art could aid him.

At last it occurred to me that perhaps the light short-sleeved India-gauze vests that he wore in the summer had some share in the causation of his agony; they were too thin either to absorb the perspiration or to protect the skin from sudden (but perniciously grateful) chills. In fact, his endeavour to keep cool was the very cause of his suffering from the heat. I accordingly advised him to wear throughout the summer the thickest long-sleeved vests made entirely of wool, such as he wore in the depth of winter. The result was the absolute cessation of his experience of "prickly heat." All last summer, and up to the present date of this, he has never felt a symptom of the recurrence of his dreaded agony.

I may further mention, as it may throw some light upon the case, that for years my patient suffered a transient attack of urticaria—itching without any outward signs—after a cold bath. Since he has taken to the constant use of hot water for all his ablutions, this irritation has never returned. It would be interesting to learn whether Indian practitioners have ever essayed to combat the excruciating anguish of "prickly heat" by any method similar to mine.

St. George's-road, N.W.

GUY'S HOSPITAL UNIVERSITIES DINNER.—A pleasant gathering of the members of the Universities of Oxford and Cambridge now at Guy's Hospital was held on Wednesday, July 16th, at the Holborn Restaurant, with Mr. J. N. C. Davies Colley, M.A., M.C., in the chair. It was decided that in order to bring the members of the Universities together the dinner should be held annually.

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

ACUTE YELLOW ATROPHY OF LIVER; NECROPSY; REMARKS.

(Under the care of Dr. ALBERT VENN.)

FOR the following notes we are indebted to Mr. John A. Shaw, the registrar:—

Harriet S——, aged seven years, a brunette, was admitted for jaundice and enlargement of abdomen. The family history was good, and the child had previously been healthy. She was taken ill eight months before with slight jaundice, which gradually increased. There had never been pain. The bowels were confined, and there was some bilious sickness after food. The child was quiet and drowsy. She had been treated for six weeks with grey powder.

On admission the body was well-nourished. The skin was of a deep-yellow-olive colour, and the conjunctivæ were deep yellow; the abdomen was uniformly distended and tympanitic, but not painful on pressure; there were no ascites. The superficial epigastric veins of both sides were prominent; the right lobe of the liver was just below the ribs; the left lobe was uniformly enlarged, its edge being well-defined and reaching three fingers' breadth below the ensiform cartilage. The urine was dark, and gave immediately bile reaction; the bowels were confined, the motions being light-coloured; the appetite was good, and there was great thirst. The lungs and heart were normal, and the odour of the breath was sickly sweet. A grain of calomel was given three times a day, and the abdomen was anointed with liniment of iodide of potassium with soap, and well bandaged.

In a few days the umbilicus was sore and inflamed, and there was some hæmorrhage from the bowels. The superficial veins had disappeared, and the abdomen was flaccid; the bowels were loose, being moved eight times in twenty-four hours.

On Feb. 26th the calomel and the liniment were omitted. On the following day a vesicular eruption had appeared, consisting of isolated spots on the sides of the abdomen and thighs, and inclined to be hæmorrhagic. The jaundice was less. Ordered a grain of grey powder three times a day. On the 28th there was hæmorrhage from the gums, lasting two days; the teeth were loose, but the jaundice was less.

March 9th.—The limit of the dulness of the left lobe of the liver was two inches above the umbilicus. The jaundice had increased again, and the child was more drowsy. On the 18th the hæmorrhage was greater from the bowels, and blood once passed without action of the bowels. The superficial veins were again appearing, and the abdomen was tympanitic. Next day one-tenth of a grain of podophyllin resin was given three times a day. On the 22nd the right lobe of the liver had diminished, and the left lobe was noticed to be smaller. One-eighth of a grain of podophyllin three times a day was ordered.

On April 5th the right lobe was much diminished, and the left was evidently getting much smaller. From March 22nd to April 7th one-sixth of a grain of podophyllin was given three times a day. On the 11th the child vomited a teaspoonful of blood, and the vomiting continued more or less to the 15th. On the 17th the child became light-headed, wandering, scarcely recognised her nurse, and was thirsty and drowsy. On the 20th she recognised no one; the pupils were dilated, inactive to light, and there was constant vomiting, with involuntary evacuations and stertorous breathing, and at length the child died. The general treatment consisted of saline purgatives and nitro-hydrochloric acid mixture.

Necropsy, forty-eight hours after death.—There was oozing of blood from the nose, mouth, and rectum. Purpuric spots existed on the legs and thighs. The cartilages of the ribs were stained light-yellow. The lungs were emphysematous at the edges, being externally of a bright-crimson tint; they were generally congested; there were no surface hæmorrhages; there were pneumonia patches at base. The heart was normal; the pericardium contained some yellow-tinged clear fluid. There was very little fluid in the peritoneal cavity on raising the intestines; on a superficial view the great omentum was found to be gathered up. The left lobe of the liver, as seen for about an inch square below the cartilages, was of a yellowish-white colour. The right lobe was not seen. There were considerable firm adhesions to the diaphragm. The liver, with gall-bladder, weighed 10½ oz. There were no superficial cicatrices. The whole was shrunken and the edges thinned; the surface was smooth; the right lobe on section was tough to cut; it presented a nutmeg appearance with yellow infiltrations; the left lobe consisted generally of yellow patches. The gall-bladder was very small, contracted, and contained a little dark-green inspissated matter. The kidneys weighed 2½ oz., and were congested; there were hæmorrhages in the cortical part. The spleen weighed 1½ oz.; on section it presented a deep-red plum colour, and was hard. Intestines: There were scybalæ in cæcum, and the walls were deeply congested; contents in some parts were greenish, in others of dark offensive feculent matter. The stomach contained dark-grumous, almost black, fluid. Brain: The dura mater was firmly adherent and of a yellow tint; the substance of the brain was apparently healthy.

Remarks.—The points of clinical interest are:—1. The continuance, but varying intensity of jaundice of surface and urine. 2. The hæmorrhage from the bowels at intervals; the pale clayey motions with diarrhœa at times. The latter vomiting of blood and hæmorrhage from gums. 3. The absence of ascites, and the absence of emaciation. 4. The low temperature; for the last three weeks usually below 98°. 5. The primary enlargement of liver; its almost sudden decrease with comatose condition supervening. 6. The combination and sequence of symptoms as usually ascribed to hypertrophic cirrhosis, and acute yellow atrophy. The points of therapeutic interest are:—1. The question of salivation, whether the bleeding from the gums was due to mercurial treatment or to the general hæmorrhagic tendency. 2. The first diminution in liver was noticed two days after the commencement of the podophyllin treatment. Was this a cause or a coincidence?

The following is a microscopical examination of the liver made by Dr. Hale White. The liver cells were much atrophied, containing a granular débris; in many cases its outline was vague and the nucleus indistinguishable. Some of the cells contained minute vacuoles, probably fat. There was evidence of interstitial hepatitis, but in no part had this proceeded to form fibrous tissue. In any field of the microscope one was struck with the large number of bile capillaries. It was difficult to say whether this was due simply to their having come close together, owing to the atrophy of the intervening liver cells, or whether they were newly formed. In favour of the latter view, they were distinctly most numerous in that part of the liver affected with hepatitis, although that had not proceeded far enough to cause contraction. There was nothing noteworthy about the bloodvessels. The microscopical appearances confirm the suggestion of the clinical history, that this was an example of acute yellow atrophy supervening on hypertrophic cirrhosis. Careful search failed to discover micro-organisms, described by Dreschfeld and others, filling up the vessels; in this respect the specimen agreed with those described by the various authors who have also failed to discover these micro-organisms.

MANCHESTER ROYAL INFIRMARY.

EXTIRPATION OF THE LARYNX FOR EPITHELIOMA: RECOVERY.

(Under the care of Mr. THOMAS JONES.)

FOR the following interesting notes we are indebted to Mr. Crawshaw, one of the house-surgeons.

J. B——, aged forty-four, was sent to the infirmary by Mr Martland of Oldham in the early part of the present year. His illness commenced two years ago with a hoarseness which soon ended in a whisper. At this time there was no difficulty in breathing or swallowing. The condition remained unchanged until last August, when he began to have sharp pains in the throat, both on swallowing and coughing. He also had dysphagia, especially when he attempted to swallow fluids.

On admission his condition was as follows:—The patient

was fairly healthy-looking and moderately well-nourished, though he had lost weight since the commencement of his illness. He spoke in a hoarse whisper. There was no evident dyspnœa, except when he lay down. He had occasional fits of coughing, particularly at night, and they generally terminated with the expectoration of a frothy tenacious mucus, which was sometimes tinged with blood. Fluids were swallowed with great difficulty, frequently they excited cough, and were eventually ejected. Swallowing efforts caused some pain, and in addition he sometimes experienced radiating pains in the head and face. On external examination of the larynx nothing abnormal could be felt, except perhaps some thickening of the right side. The larynx moved freely during deglutition, and it readily yielded to lateral pressure. An enlarged gland could be felt in the anterior border of the sterno-mastoid opposite the thyroid cartilage. A laryngoscopic examination was made by Dr. Dreschfeld. Projecting from the back of the epiglottis, a little to the right of the median line, there was a small-pointed tumour, about the size of a bean. Its attachment was broad and sessile, and there extended from it some thickening which involved the aryteno-epiglottidean folds, especially the one on the right. The movements of the vocal cords were impeded, the loss of motion chiefly affecting adduction, and was more marked on the left side.

After remaining in the infirmary for a few days, the patient went home. When he returned, after an absence of some weeks, a marked change for the worse was noticed; all the symptoms—the hoarseness, dyspnœa, cough, expectoration, dysphagia, and the pain—had decidedly increased; he had also become very sallow and pale, and had emaciated considerably. The examination with the laryngoscope was repeated. The growth springing from the epiglottis was much larger, while its surface had become irregular and papular. The thickening in its immediate vicinity had also increased, and that which involved the right epiglottidean fold now formed a very distinct mass, which concealed the right vocal cord. The left cord could be seen; it still retained some movement. No ulceration could be detected. The pharynx was apparently free. External examination disclosed an increase in the thickening of the right side, previously noted. In any attempt to pass a large-sized œsophageal bougie, an impediment was encountered in the lower part of the pharynx. Instruments of a smaller size were admitted without any difficulty; their withdrawal, however, was followed by the expectoration of blood.

April 22nd.—Preliminary tracheotomy was performed, an opening being made in the trachea above the isthmus of the thyroid; great relief followed this procedure, no unfavourable symptoms resulting. Four days later (April 26th) the whole larynx, together with the first ring of the trachea, were removed. The patient being under the influence of chloroform, the ordinary tracheotomy tube was removed and one of Trendelenburg's substituted. A vertical incision was made in the median line of the neck, reaching from the hyoid bone above to the tracheotomy incision below. The structures were carefully separated from the front of the thyroid cartilage, which was then divided and the two halves separated. The interior of the larynx thus brought into view was found to be almost completely filled with a new growth. The mass reached upwards to the epiglottis and downwards as far as, and to a certain extent into, the trachea. The extent of the growth made it evident that nothing short of complete extirpation would be of any avail. In order to do this, more room was required, and it was obtained by prolonging the incision downwards to the sternum, then dividing several more rings of the trachea so as to push the tracheotomy tube further down. This being done, the soft parts were now dissected off the sides of the thyroid cartilage and its attachment to the cricoid severed. The left half of the thyroid was then removed, its remaining attachments being divided with scissors. The right half, including the epiglottis, was treated in the same way. The laryngo-pharyngeal septum was found to be so extensively infiltrated that it was impossible to separate the larynx from the pharynx, so the whole of the anterior and lateral walls of the latter were taken away, only a portion (about an inch wide) of the posterior wall being left. This was subsequently divided and sutured to the margins of the skin incision. The cricoid cartilage, together with the first ring of the trachea, were next excised. The upper end of the trachea was fixed to the skin by a carbolised silk suture on each side. Above the points at which the œsophagus was attached to the skin there was a large cavity which communicated with the mouth. It was washed out with a solution of chloride of zinc (forty grains to the ounce), and afterwards plugged with iodoform gauze. During the operation numerous small arteries were divided, necessitating the application of twenty-two ligatures. Besides this, several vessels were torsioned. The patient took the chloroform well, and there was no special difficulty in any part of the operation. There was a marked degree of shock afterwards. An enema containing an ounce of brandy was given, but not retained. A second one half an hour later remained. The patient's bed was surrounded by a tent, the atmosphere in which was heated and moistened by means of a steam kettle, and the wound in the throat was covered with warm sponges constantly renewed. By the evening—i.e., twelve hours after the operation—the shock had to a great extent passed off. There had been no sickness. The pulse was good and the breathing quiet. The temperature was normal; all the enemata were retained. There was slight oozing of blood from the wound.—27th: The patient passed a very comfortable night, but was rather more feeble. The face wore an anxious expression, the pulse was weak and compressible, and the temperature still normal; slight cough, with expectoration of stringy mucus. In the evening the patient looked brighter, and the pulse was decidedly improving. Since the operation he had been fed exclusively by enemata. A tube was passed through the œsophageal opening in the neck and half a pint of milk introduced into the stomach. Temperature normal.—28th: Has had a good night, yet is depressed this morning. Milk given by the œsophagus causes occasional coughing and is sometimes brought back. Free discharge of mucus from the tracheal opening. During the day he had four pints of milk, one pint of beef, jelly, and two eggs by the œsophageal opening. The daily records show a slow and gradual improvement in the general condition. Our principal troubles arose from the saliva gaining access to the trachea and exciting a great deal of cough. Fortunately we overcame the difficulty by introducing one of Foulis's tubes into the trachea. This accurately fitted the opening and effectually prevented the passage of any secretions.

On May 4th the sutures attaching the œsophagus to the skin were removed, and the upper extremity of the tube allowed to fall back. This permitted a re-establishment of the communication with the mouth, temporarily suspended with the view of facilitating the introduction of food. On the 6th the patient was still progressing favourably, no unpleasant symptoms of any kind having made their appearance. The temperature remained normal. He looked bright and cheerful. A note was made of a swelling the size of a walnut, which was situated in the lower part of the neck at the posterior margin of the left sterno-mastoid muscle. It first appeared about six days after the operation, and attained its present size in two days. This fact rendered the inflammatory nature of the swelling probable. It remained stationary for several weeks, and eventually the withdrawal of a few drachms of sero-purulent fluid finally determined its true character.—15th: Since the date of the last observation patient has been making very rapid progress, and for the last three days has been getting up in the afternoons. The discharge from the wound is diminishing, and the parts look healthy.—25th: The cavity has contracted to such an extent that a finger can scarcely be passed upwards into the mouth. By the aid of a large drainage-tube having one end at the back of the mouth, and the other in the œsophagus, milk can be easily swallowed, without any of the fluid appearing in the neck.

The patient went home on June 14th. He still wears one of Foulis's tubes, and all nourishment is taken by the mouth. During the last three weeks he has gained over a stone in weight. An examination of the parts removed was made by Mr. Young. The whole of the mucous membrane of the larynx and lower part of the epiglottis presented an irregular, corrugated appearance, with here and there slight ulceration. It was so greatly thickened that the cavity of the larynx was almost obliterated. On the left side the true vocal cord and the orifice of the ventricle were discernible, but the normal appearances were in every other respect destroyed. The new growth was fairly limited inferiorly at the lower border of the cricoid cartilage, though below this the mucous membrane was not thickened. Above it was not clearly defined, for scattered nodules extended into the pharyngeal mucous membrane. Microscopically the growth presented the characters of a pavement-celled epithelioma.

Medical Societies.

EPIDEMIOLOGICAL SOCIETY.

AT a meeting of this Society, held at 11, Chandos-street on July 9th, Inspector-General Lawson in the chair,

A short paper on the Revaccination of School Children was read by Mr. R. D. R. SWEETING, Medical Superintendent of the Western Fever and Small-pox Hospital. After observing that consideration of the large number of vaccinated children under fifteen years of age admitted into the small-pox hospitals was not sufficiently recognised by pro-vaccinators, though constantly taken notice of by anti-vaccinators, he brought forward statistics of such cases admitted into four of the large small-pox hospitals of London during 1881, 1880, 1879, and part of 1878. The numbers were divided into two classes, well and imperfectly vaccinated, and it was seen that 72 per cent. belonged to the latter class. A note was made of the difference of area standard between the Local Government Board and the Asylums Board, and the inference drawn that were the more rigid standard of the former adopted, the numbers of the well vaccinated would be found to be less. The age distribution of the cases was then examined, division into the three first quinquenniads of life being made, the result being that both the gross numbers in each age group and the totals of the two subdivisions were found to increase in the same progression with the age, this being roughly as 1 : 4 : 8. (It was incidentally remarked that this ratio showed the greater protection afforded under five years than over.) After drawing attention to the fact that it was not only the numbers of the imperfectly vaccinated that increased in a mathematical proportion with the age, but also those of the well vaccinated, a renewal of the operation was advised between the ages of ten and fifteen at the latest, and earlier if any special reason exists. Upon this question the opinion of Dr. MacCombie is quoted favourably. School attendance was looked upon as a convenient and readily applicable opportunity for the purpose of such revaccination, and upon this matter a recommendation of the Homerton Committee in 1876 and a valuable Order of the Illinois (U.S.A.) State Board of Health of 1882 were quoted in full. This latter is addressed chiefly to school teachers, and makes it imperative that they should keep a vaccinal record of every scholar, all of whom must present certificates of proper protection, this being very carefully defined. A similar vaccinal registration was then recommended for the London School Boards, to be supplemented by periodic inspection, and compulsory revaccination of the imperfectly protected. The suggested central authority would be either the Education Department, the Local Government Board, the proposed municipality, or, lastly, the hospital authority recommended by the Hospitals Commissioners.

Mr. C. E. PAGET then read some Notes on the Death-rate from Small-pox in the City of Chester in 1774, of which the following is an abstract. He stated that he was desirous of bringing before the Society the records, contained in a report on the city of Chester, of the behaviour of small-pox during an epidemic prevalence of the disease in 1774. From the tables in the report the population appeared to have numbered 14,713, and the average annual mortality from small-pox was estimated at 49, or 3·3 per 1000 of population. In 1774 the total number of deaths was 546, of which 202 were from small-pox, or 13·7 per 1000 of population. The total number of persons attacked by small-pox was 1385, so that, as stated in the report, there died 1 out of 6⅞ of those attacked, or at the rate of 14·5 per cent. The incidence of the disease appears to have been exceptionally large in the last three months of the year, 130 deaths out of the 202 being recorded during that period. It must be a matter of surprise that within such recent times the death-rate from small-pox should have been so enormous, for, taking the average annual mortality from this disease in Chester as 49, it was seen by the tables of the report that one-eighth of the whole annual mortality was from small-pox. The report further states that in January, 1775, there were in Chester only 1060, or 1 out of every 14, who had not contracted small-pox, a proportion quite as remarkable as that of the average mortality from the disease; and the report commences with the statement that "the tables prove Chester to be healthy in such an uncommon degree as will astonish those who are best acquainted with the general state of mortality in large towns." It is interesting to note the views of a physician of those times as to the possibility of controlling by inoculation the ravages of small-pox, for Jenner's attention was directed to cow-pox only in 1775, and his first decisive experiment in vaccination was not performed till twenty-one years later. Dr. Haygarth believed that if inoculation were universally practised in Chester the mortality from small-pox would be reduced from 49 to 4; but probably this estimate was too low, and it is fortunate that inoculation was not practised so vigorously as to delay the introduction of vaccination. He estimated, however, from his tables that the proper time for the performance of inoculation was between the first and third months of infancy, a time fully agreeing with that which has been proved to be the best for the performance of vaccination, and he pointed out that the total 202 deaths from small-pox already referred to were among children under ten years of age. The comparison, therefore, of the mortality from small-pox at that date with that which has been recorded of late years will not be found wanting in interest, for the infant mortality from this disease has now been enormously reduced, and the mortality among adults appears to arise chiefly through their not being revaccinated.

Dr. CORY also presented the report of the Special Committee appointed to investigate the Conditions affecting the protection against Small-pox afforded by Vaccination, which was ordered to be printed.

In the discussion which followed, Surgeon-General Manifold, Drs. Pringle, Cory, Willoughby, and Messrs. Corney and Shirley Murphy took part.

ACADEMY OF MEDICINE IN IRELAND.

AT a meeting of the Pathological Section on May 2nd, Mr. ARTHUR BENSON read a paper on the Nature of Jequirity Inflammation, recounting a series of experiments on which he had been engaged since January last. He concluded that the bacillus found in the infusion had nothing whatever to do with the production of the inflammation, but had not yet satisfied himself as to its real nature. He could produce the characteristic membranous ophthalmia with jequirity powder, with freshly made cold infusion, with infusion in which the bacilli had developed, with the same after they had died, and with an infusion more than eight weeks old, but still swarming with micro-organisms of various kinds; while he had failed to produce any results by inoculation of the discharge or membrane caused by jequirity. Nor could he in the membrane or discharge find any bacilli whatever, though he had made numerous observations at all stages of the affection. In these respects his observations were confirmed by those of Neisser, Klein, Salomonsen, and Holmfield. He had latterly tried the effects of powdered jequirity dusted on callous ulcers of the leg, and found that a similar membranous inflammation was produced on them as in the conjunctiva, the membrane being easily detached from the ulcerated surface. The stimulation caused by the application seemed decidedly beneficial in a certain class of ulcers, and even in vascular ulcers the application of the powder produced hardly any pain whatever.—The PRESIDENT said the communication was most interesting. The merit of a man who demolished a false theory was only second to that of a man who established a true one.—Mr. STORY remarked that when jequirity was first introduced into ophthalmic surgery as a cure for granular ophthalmia, it was conjectured by oculists that the cause of the inflammation was micro-organisms. He, too, for a long time believed that bacilli were the cause of the ophthalmia, but since Dr. Benson's experiments he had modified his opinion, and did not regard that theory as proved.—Dr. JOSEPH KENNY believed that Dr. Benson's observations were at all events coeval with those of Klein. In the North Dublin Union Workhouse the drug was tried on ulcers with strongly marked improvement as the result, and on the whole he was encouraged to proceed with the investigation of the effects of the drug in cases of ulcer.

Mr. P. S. ABRAHAM, in a communication on Scapulo-Humeral Dislocation in the Horse, said that dislocation of the shoulder-joint is very uncommon in the horse. Most writers on veterinary surgery do not allude to such a lesion; others deny its possibility; and only one or two mention cases in which the accident had happened. No description had been found of an actual specimen, and probably the example before the Academy was unique. The humerus was

Digitized by Google

dislocated on to the dorsum of the scapula, the head being three and a half inches away from the glenoid surface. The outer edge of the latter was broken off and forced up. The capsular ligament was ruptured, but none of the muscles or their tendons, that of the flexor brachii being only much stretched and changed in direction. Anchylosis had commenced between the humerus and scapula in their new position. The horse took a fence intemperately and fell across a narrow bank at the other side of the ditch, with its off fore-leg under it. When got to stand up the deformity was observed, but the horse was able to put the foot to the ground, and was led a distance of three miles and a half to the nearest station and brought to Dublin. The veterinary surgeons were confident that some muscle or muscles were ruptured, and that the joint was not dislocated. They ridiculed any attempt at reduction. A severe blister was applied, and subsequently a leather shield was fastened tightly on. The strap caused a sore on the withers, and ten weeks after the injury lockjaw set in.—Dr. BENNETT asked whether veterinary surgeons regarded this dislocation as an impossibility in the cow. The anatomy was similar to that in the horse, but the conditions for the occurrence were somewhat less favourable.—Mr. ABRAHAM said the joint in the cow, though similar, was not quite the same as that in the horse. The top of the humerus was not so large in the cow, and the whole shoulder was not so movable as in the horse. One method of reduction in the case of the cow was by putting the hoof of the leg over the horns and driving the animal until the dislocation got in of its own accord.

Mr. STORY exhibited a rare Tumour of the Orbit about the size of a small pea, which he had removed from a young woman aged twenty. It had existed from earliest childhood, and had lately increased in size. The tumour lay beneath the lower lid towards the inner canthus, was freely movable in all directions, strong and hard to the touch, and was covered by slightly discoloured skin. When the patient stooped, laughed, cried, or took violent exercise, this patch of bluish skin became swollen. When the superjacent soft parts were divided the little tumour came out without further interference. On section it was found to be solid and formed of a series of irregularly concentric lamellæ, which microscopical examination showed to consist of fibrous tissue and calcified matter of unknown origin, along with cellular conglomerations of an indefinite character. Nothing resembling either bone or cartilage existed in the tumour, its stony hardness being due to new calcification. He considered the tumour to be a phlebolith, the history of the case and the pathological appearances agreeing with that view. The only tumour at all resembling it hitherto described was one removed by Fano, and described by that author as an osteo-fibro-cartilaginous growth.—Mr. ABRAHAM said he had examined the section prepared by Mr. Story, and believed that he had come to a correct conclusion as to the tumour being of the nature of a phlebolith. There was nothing bearing the form of cartilage cells in the growth. It seemed to consist of a kind of fibrous tissue which had become calcified. The inside consisted of an irregular amorphous mass of material, and it was impossible to say what that was.—Mr. BENSON thought the tumour in the first instance was a nævus.—On the motion of Mr. STORY, seconded by Dr. BENNETT, the specimen was sent to the Committee of Reference.

Dr. LENTAIGNE having submitted a specimen of Multiple Diverticula of Large Intestine, said it was wonderful that no evil effects had resulted. According to the opinion of Dr. Habershon, the formations in such cases were the result of constipation and the attempts of the intestine to expel the fæces. In the specimen the longitudinal fibres were very much hypertrophied.

Mr. THOMSON showed a case of Fracture of the Head and Articular Surface of the Tibia. The patient had fallen from a height, reaching the ground on his feet, and the bone was fractured by the weight of the body communicated by the condyles of the femur. He showed that this fracture was not described in the ordinary books of reference. Heydenreich, in 1877, referred to four cases in the continental museums. Professor Gordon of Belfast mentioned that there were three specimens in the museum there, and Professor Bennett of Dublin had secured an excellent specimen from the dissecting-room, the injury in that case having been recovered from.—Dr. STOKES said a much smaller amount of force would produce fracture of the tibia when the knee was flexed than when it was in a straight position, because there was a much smaller amount of curvature of the condyles.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

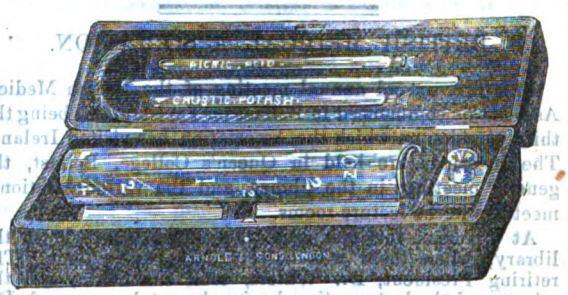
A MEETING of this Association was held on July 24th at the Medical Society's Rooms, Cavendish-square, Surgeon-Major Evatt, M.D., President, in the chair. The hon. secretary, Dr. Alder Smith, read the minutes of the last meeting. The Council had decided that the annual general meeting should be held about Easter, 1885. Another ordinary meeting is to take place before the Christmas holidays.

The PRESIDENT, in opening the proceedings of the afternoon, prefaced Dr. Andrew's paper by a few remarks on some of the objects of the Association, which now numbers fifty-eight members. Dr. Evatt said he had long considered that the footing of medical officers of schools was not established on a satisfactory basis, and this Association was calculated to strengthen the hands of such medical officers. He thought it was a grand part of the duty of the medical officers to instruct boys on the dangers which assailed them on their entry into adult life, and Miss Ellis Hopkins, who so much sympathised with these aims, had congratulated him on the course he adopted at the Woolwich Military Academy. With regard to infectious diseases in large public schools, he considered that much good would result from a full discussion of the whole subject by members of the Association. In his opinion no man was better fitted for the head mastership of a school than a talented medical man, and he believed a new priesthood was coming forward in the form of medical men capable of discharging also the duties of head master.—Dr. ALDER SMITH then read the report of the Council, which set forth the objects, constitution, and printed rules of the Association. These were unanimously adopted by the meeting.

Dr. JAMES ANDREW, physician to Christ's Hospital, read a paper on the Managment of Epidemics of Infectious Diseases in Schools. He first dwelt on some general considerations bearing on the necessity for such an Association. It had been said that societies were so numerous that unless good reasons existed for founding a new one we had no right to add to the number. The principle of the division of labour may be carried too far, and we ought to be careful not to make artificial distinctions. To justify the creation of a new Association, the importance of the field of labour, practically or theoretically, or both, ought to be admitted on all sides. Further, there should be something special in the objects of the new body. Special qualifications should be required, or such as are only to be obtained by special training, so that things may be better done. In the care which was necessary for the welfare, physically, morally, and intellectually, of our youth he saw a sufficient justification for the establishment of this Society. Degeneration of the physical basis of life certainly could not take place without corresponding lowering of the mental and moral constitutions. The duties of medical officers of schools were becoming more and more widely separated from those of the general practitioner, and problems arose before them requiring the highest practical knowledge and sagacity in order to be promptly and efficiently solved. It must be confessed that at some schools a medical officer exists only in a most rudimentary form. The first necessity of a public school is efficient medical supervision, and this is impossible without a recognised medical head. It was constantly happening that masters of schools refused to recognise dangers to health resulting from many infectious diseases and overwork. Next, it was imperative that a recognised medical canon which should enlighten and guide all medical officers should exist; by such means the ignorant may be taught and the eccentricities of the otherwise competent smoothed out. Dr. Andrew next considered the nature and scope of work which ought to be undertaken by the Society. The opportunity afforded for the study of the nature and history of diseases amongst large numbers of boys congregated together was not one to be lost. The period of incubation was a subject which required much investigation. He opined that this period in scarlet fever was by no means so uniform as some books taught. We knew that the period of incubation varies greatly in small-pox after inoculation; the determination of the maximum and minimum periods of latency ought to be definitely ascertained. With regard to the presence of symptoms during the period of incubation from which a diagnosis might be made, he thought a large field of observation was opened.

Digitized by Google

A careful examination of the conditions which gave rise to different types of the same diseases would repay the observer. Epidemics of scarlet fever and typhoid fever varied greatly in the intensity and characters of the predominant symptoms. Diphtheria, especially in relation to the paralysis which occurred afterwards, was also, in his opinion, a case in point. A study of the relationship of different forms of disease to each other and their influence on each other, as rheumatic fever and scarlet fever, variola and typhoid, was a promising field of inquiry. Whether the liability to take small-pox again or after successful vaccination were due to want of care in the vaccination, or whether, as Sir James Paget suggested, a fresh modification of constitution might be brought about by some disease subsequent to vaccination, was also a fit subject for investigation. Mention was made by Paget of the occurrence of typhoid fever, in 1850, in a town near Oxford; when small-pox broke out in 1865 it was shown by Mr. Daniel that out of 616 persons then revaccinated the result was unsuccessful in many, but by no means in all, and it also came out clearly that the successful revaccinations occurred chiefly or almost wholly among those who had had typhoid fever previously. Dr. Andrew was inclined to believe that a severe attack of typhoid fever did away with the protection afforded by vaccination. The development of inherited peculiarities, as well as the best mode of correcting hereditary diathesis, were also worthy subjects of observation. The best plan of erecting school buildings and dormitories, and the question of separate establishments for boys under and over twelve years, as was done at Christ's Hospital, with a view of diminishing the frequency and severity of epidemics in the London house, were also problems for consideration. Information, too, was wanted as to what were the best means to be adopted in case of an epidemic of scarlet fever and measles. In an instance in which the virus has been imported, perhaps complete isolation of the sufferers and possible carriers of infection would be effectual, and quarantine ought to extend as long as the maximum period of incubation of scarlet fever. In many instances there would be some difficulty, because no certain diagnosis would be possible. When the epidemic is raging, the question, Ought the school to be broken up? will arise. Dr. Andrew confessed that he permitted the parents to take away their boys if they chose. Another matter was the importance of careful disinfection of the clothes; in many schools adequate means for proper disinfection did not exist. —Dr. FULLER (St. Nicholas's College, Lancing) said that in many schools there were no proper means of isolation. The maximum limit of the period of incubation of scarlet fever, in his experience, might safely be put at fourteen days, and he always enforced quarantine for that space of time. He had waited for thirteen days without having a fresh case, but even then had been disappointed.—Dr. INGLE (The Leys School, Cambridge), Surgeon-Major LEVER (Military College, Oxford), Dr. ALDER SMITH, and the PRESIDENT, also made some remarks.—Dr. FYFFE (Clifton College) spoke of the value of a good sanatorium attached to a school. He asked how the origin of a case of scarlet fever occurring on the nineteenth day after another case could be explained. Dr. Clement Dukes had said that after eight days there need be no fear of new cases arising.—Dr. EVATT said that in a recent epidemic of measles at Woolwich he turned all his boys out into tents and marquees with satisfactory results.—Dr. FYFFE said that at Clifton he had three sanatoria, one for non-infectious cases, another for contagious skin diseases, and a third for acute specifics; but even here difficulties were to be encountered when the nature of a case was doubtful, so that in addition an observation room is required.—Mr. HOLDERNESS (Eton) thought that certificates stating that boys had not been in contact with contagious affections for a week or ten days before their return to school ought to be given.—Dr. ALDER SMITH said that he wished to state most strongly that every public school ought to be under the control of an undivided medical responsibility, with full power to act immediately occasion required it. It was well known that some masters were not nearly so particular as others. Moreover, it was unfortunate that so many differences of opinion existed amongst medical officers themselves. This fact was strongly illustrated by a review of the fifty replies which had been received to a circular form of inquiry drawn up by Dr. Alder Smith. For instance, in answer to the question, What length of time (dating from the appearance of the rash) do you insist upon before the pupil is allowed to rejoin school? the time given varies for scarlet fever from one month to three months, and the same difference of opinion was found by going through the whole list of questions proposed in the circular form of inquiry.—Mr. COOMBS (Bedford County School) was strongly of opinion that certificates from parents or guardians were not of the least value, for infectious disorders might be caught whilst the pupils were *en route* to the school.—Dr. DOLAN (Shibden Industrial Schools) said that quarantine for three weeks was an excellent regulation when any doubt existed as to whether the boys came from an infected district.—Dr. BRETT (London Orphan Asylum) did not think certificates were of much value.—Dr. JONES (Epsom College) considered that certificates were of some good, though not of much importance. He was sorry to have to say that the parents did not always write the truth.—Mr. STEDMAN (St. John's Foundation Schools) also joined in the discussion.—Dr. SHELLY (Haileybury) thought that every school should have some place of isolation for the detention of doubtful cases. With regard to the certificate from the parents, stating that the boy had not been in contact with infection for a certain period before returning to school, he said that personal experience made him absolutely sure that it was of no value. He also spoke on the question of disinfection of clothes, and said that he believed the disinfection of the clothes of a measles patient might be accomplished by exposure to sunlight and air. German measles was in his experience much more difficult of disinfection.



The following resolution was moved by Dr. ALDER SMITH, seconded by Dr. EVATT, and unanimously carried:—"That the Council be requested to bring forward at the next meeting a series of resolutions on the best methods for the prevention of epidemic diseases in schools, and that the business of the meeting be the discussion of the resolutions with a view to their adoption." A copy of this resolution will be sent to every member at least three weeks before the next meeting takes place.

Dr. Thursfield (Leamington College), Dr. Fletcher (Highgate Grammar School), Dr. Pike (Malvern College), Dr. Jones (Epsom Medical College), and Dr. Tomkins (Female Orphan Asylum) were elected members of the Society.

New Inventions.

THE COMPANION URINARY CASE.

THE above-named case contains in very compact form all the appliances usually required in the examination of urine. It may be briefly described as follows:—An ordinary cylindrical two-ounce glass measure has closely fitted into it a test-tube, and into this again is placed a urinometer in case. At one end is a small spirit-lamp. Litmus and turmeric papers fill up a groove running lengthways. In the lid is a

gum catheter, a glass stirring rod, and two delicate long glass-stoppered bottles for caustic potash and picric acid. With the contents of this case the urine can be drawn off, the amount measured, and the specific gravity and reactions to blue and red litmus paper taken. With the two chemicals, caustic potash and picric acid, and the aid of the spirit-lamp, pus, albumen, and sugar may be examined for. There is no strong acid to ooze out in carriage. The whole is contained in a case measuring seven inches long, one three-quarters deep, and the same in width. It has been made for me by Messrs. Arnold and Sons of Smithfield.

T. FREDERICK PEARSE, M.D.

A NEW LEVER WITH TRACTOR BLADE.

THE instrument here represented has been recently made by my direction by Messrs. Meyer and Meltzer. When closed it is of the form of an ordinary vectis, but with this modification: it has applied to its inner surface, by means of a sliding screw running in its handle and shank, a similarly shaped blade to the outer one, and this inner blade can be projected beyond the outer one after the instrument is applied in a closed condition to the extent of two inches and a half or less, according to need. The chief novelty of this instrument is the augmentation of the lever and tractile power of a vectis by the projection of an inner movable blade. The cases in which this instrument will be found useful are: in breech or footling presentations, where there is delay in the delivery of the after-coming head, especially in those cases where, owing to the presence of the shoulders causing an obstacle to locking of the blades, the forceps cannot readily be applied, its great power as a tractor being then eminently useful. It is also efficient in cases of face presentation, the occiput being easily brought down by means of this instrument, and also in some cases of occipito-posterior presentations in which it is desired to aid rotation of the vertex. It should be introduced closed as an ordinary forceps blade, the end of the fenestrum being carefully guarded and directed by the fingers of the left hand inside the cervix. When in proper position, the screw is pressed, and the inner blade made to project to the requisite distance. As the blade is projected by simple pressure, the resistance can be estimated, and the chances of injury to the soft parts reduced to a minimum.

Tavistock-square. LUKE ROBINSON, M.D. Cal., &c.

THE ALBERT SATCHEL.

THIS is one of the best satchels for tourists' use we have seen. It is made so as to combine the advantages of a knapsack and handbag, is thoroughly waterproof, and weighs about 16 oz. It will, we believe, be a welcome addition to the pedestrian's equipment. The manufacturers are the Army Rubber Company, Brompton-road, Knightsbridge.

BRITISH MEDICAL ASSOCIATION.

THE fifty-second annual meeting of the British Medical Association commenced in Belfast on Tuesday, this being the third occasion on which the Association has visited Ireland. The meetings are held in Queen's College, Belfast, the general meetings in the library, and the various sectional meetings in the lecture-rooms.

At 3 o'clock the first general meeting was held in the library, when there was a very large assemblage. The retiring President, Dr. Waters, took the chair; and the minutes of the last meeting having been taken as read, Dr. Waters said that, as the term of his presidency was about to expire, the only remaining duty which he had to perform was to introduce his successor to the chair which he had the honour of filling. The past year had not been an uneventful one in the history of their Association; on the contrary, it had been marked by the enactment of laws in reference to the Society which had produced material alteration, making the executive more responsible than the whole body. The change was one which, he believed, would tend to the increased prosperity of the Association. To that body and the committee of council, which had guided the council to its present position of strength and usefulness, they owed, in his opinion, a large debt of gratitude. He congratulated them on the great prosperity of their Society, and the steady increase of their members—an increase which bade fair, in the course of years, to include within the Association almost every member of the profession in this country. Dr. Waters concluded by thanking them for the honour they had conferred upon him, and by introducing Prof. Cuming, Belfast, the president for the ensuing year.

Dr. Cuming having taken the chair, a cordial vote of thanks was given to Dr. Waters, and he was elected a vice-president of the Association for life. From the report we gather that the invested funds of the Association now amount to over £17,000, and the number of members to nearly 11,000. The revenue of the Association for the year ending Dec. 31st last was £20,545, the expenditure £18,141, leaving a surplus of £2404. Dr. Wade having resigned the post of treasurer, Mr. Macnamara (London) was elected in his place. At 8 o'clock the meeting reassembled in the library, which was lit up with the electric light, and was crowded with members who had come to hear the President's address.

At the conclusion of Dr. Cuming's address a vote of thanks, proposed by Dr. Douglas Powell, and seconded by Dr. Grimshaw of Dublin, Registrar-General of Ireland, and a native of Belfast, was most heartily accorded to him. A discussion on some notices of motion followed, and the meeting concluded at 10.30. Amongst the distinguished foreigners attending the meeting are Professor Sayre (New York), Dr. Jacobi (New York), Dr. Cordes (Geneva), Dr. Jones (Chicago), Dr. Moore (Rochester), Dr. Shoemaker (Philadelphia), Professor Zehender (Rostock), Dr. Pozzi (Paris), Professor Gayet (Lyons), Dr. Dujardin-Beaumetz (Paris).

On Wednesday morning, at 9.30, Professor Sayre (New York) gave a demonstration in the anatomical theatre of the College of his plan of treating curvature of the spine. There was an immense audience, who paid marked attention to the professor as he explained and illustrated his well-known method of treatment.

At eleven o'clock the second general meeting was held when Mr. Wheelhouse (Leeds) resigned his post of President of the Council and was elected a vice-president of the Association for life. Dr. Balthazar Foster (Birmingham) was elected President of the Council in his place. An invitation was presented from the medical men in South Wales asking that the Association should meet in Cardiff next year. This was cordially agreed to, and Dr. Edwards was chosen President-elect. Dr. Ord then delivered his address, at the conclusion of which a cordial vote of thanks, moved by Dr. Waters (Liverpool), and seconded by Professor Gairdner (Glasgow), was accorded to that gentleman.

The meetings of the sections opened on Wednesday afternoon, when addresses were delivered by Dr. Smith, Dr. Godson, Professor Greenfield, Dr. Maclagan, and Sir J. Mac Cormac. Special discussions were opened by Mr. Lawson Tait and Dr. G. Johnson. In the evening there was a brilliant conversazione in Queen's College, two thousand guests being present.

MEDICAL MEN FOR COLONIAL SERVICE.

A BRIEF paper was read by Dr. Dyce Duckworth at the First Intercolonial Medical Congress, held in Amsterdam last year, on the supply of sound practitioners for the English colonies. The author of the paper is of opinion that encouragement should be given to young men of good ability to come forward for colonial service, and that this end might be served by the institution of scholarships in general literature or science of such value that the costs of medical education might be, at all events, partially defrayed, it being suggested that the funds for this purpose should come from the Colonial Department of the Government. The study of physics and chemistry is urged in opposition to a detailed knowledge of anatomy, physiology, and botany. To protect properly qualified men, Dr. Duckworth considers that it ought to be the care of the mother country or of the local Government to prevent imperfectly educated practitioners from practising in a colony. He thinks it important to recommend that no colonial practitioners should commence work in tropical regions under the age of twenty-three or twenty-four years. Statistics seem to prove that a better standard of health is maintained if tropical service is begun at this time of life, and that Europeans are thus enabled to resist the special risks of trying climates with greater prospect of success.

THE LANCET.

LONDON: SATURDAY, AUGUST 2, 1884.

WE confess to announcing the miscarriage of the Medical Bill with a considerable sense of relief. For some weeks past it has been too evident that if the Bill was to pass at all it would do so in a gravely mutilated condition. Hence our relief at its disappearance. But let no one construe our confession of relief into one of satisfaction. We are filled with shame and the sense of disappointment, qualified only with the conviction that what has happened is better than what might have happened. The present system of numerous and rival bodies granting half diplomas remains condemned and disparaged before the country and Parliament. It has not been slightly altered, so as to look something different, as it might have been if the Ministry had yielded—as it threatened to do—to the pressure that was so discreditably applied to it. When a great accident happens, the only satisfaction to be got is in a diligent search for the answer to two great questions—What is to blame? and Who is to blame?

To take the first question—*What* is to blame for the fact that an obvious reform, recommended by a Royal Commission of the highest authority, regarded by the Medical Council itself as the only thing to remedy the existing evils, and demanded for forty years by the medical profession, has been again defeated? The fact itself is of the gravest import. The reform desired is not a revolution. It is one which has been repeatedly attempted by the Conservative party, and which the Duke of RICHMOND besought the Government to carry through without further delay. It is only fair to admit that for the failure of legislation one of the most obvious and simple causes is the absurd state of Parliamentary procedure. The forms of the House of Commons invite obstruction, and reward it. At every stage encouragement is given to the least distinguished members to mar the work upon which Ministers and Members of Royal Commissions may have spent years. Leave has to be taken to bring in a Bill. It has to be read three times. A motion has to be made to go into Committee, and various other motions. On all of these occasions speeches may be made, amendments moved, and obstruction practised. The 652 members may all try their hands at an amendment, and intimidate Ministers by a show of opposition. But perhaps the greatest absurdity in Parliamentary procedure is the rule that the progress made with a Bill in one session is not to count at all in the next. The promoters of the Bill have to begin again *de novo*. The Medical Bill, for example, has passed the House of Lords, and has been read a second time in the House of Commons. Its principles have been accepted in both Houses. If next year it could be taken straight into Committee in the House of Commons, and the Minister in charge had the time and the courage to place boldly before the House the chief points of the evidence put before the Royal Commission, the Bill would pass by a large majority. But according to the present rules of procedure, the Bill would, in all probability, not reach the Committee stage of the House of Commons till the end of July, and the Minister would be driven to an undignified system of haggling with exacting or unpatriotic members, and the process of bargaining would go on till the very marrow of the Bill would be sold, and nothing left for anyone to care for. The enemies of medical reform may well congratulate themselves on the perfection with which these rules for preventing legislation have been carried out. But the result is terribly humbling to the strongest Government of modern times, with a majority of 130 at its back. On the theory that the House of Commons is an excellent club, and legislation a mischievous thing to be discouraged, the blank report of sessions is of course all right. But this theory will not long command for the House of Commons the respect of earnest men who see great evils to be remedied, and the utter impotence of Parliament to deal with them. Verily, Mr. GLADSTONE lately struck the right nail on the head when he said that, beyond all other reforms, that which is most needed is the reform of procedure in the House of Commons.

But, coming to our second inquiry, *Who* is to blame? no fault of the rules of procedure will exonerate those who take advantage of them, or who abuse their influence in the House to prevent wholesome and reasonable legislation. There were pages of amendments placed on the order papers which we have no hesitation in saying were entirely without justification, and, if not meant to waste time and stop the Bill, were singularly well fitted for that purpose. Take as an illustration—by no means the worst—an amendment in Dr. LYONS' name, proposing to create Medical Lords of Appeal with the rank of Barons, and votes and seats for life in the House of Lords. Can a man of Dr. LYONS' sense really think to alter the constitution of the House of Lords by a clause in a Medical Bill, or can he think to increase respect for medical representatives in Parliament by giving utterance to such impracticable propositions? If Dr. LYONS had spent half as much of his excellent intellect in supporting the Government Bill as in devising this amendment, he would have compelled the admiration of the profession. But the chief culprit, in our opinion, for the last and greatest failure in medical legislation, is Sir LYON PLAYFAIR. Everything was going smoothly, and promised success, till his amendment, dealing a deadly blow at the very essence of all wholesome and just legislation, was propounded. Sir LYON PLAYFAIR had last year, with his university, entirely accepted the principle that university students, like all other students, should pass the Final Board. The very numbers taught and passed by the Scotch universities constitute an argument why they should cheerfully accept this principle. Their degrees would have gained in public estimation by their doing so. Now they appear as shirking a slight test, and give Mr. SIMON additional ground for his taunt that their examinations are no higher than a qualifying examination ought to be. Sir LYON PLAYFAIR knows that the profession had set its mind on fair play all round—the subjecting of graduates and non-graduates to one common test. He knew that when he began to tamper with that principle he was parting company with the profession and grievously disappointing it. His speech, as we have shown, was full of damaging insinuations against the Bill, founded on most inaccurate data and unsound arguments. He spoke as an ex-professor, and in no sense as a medical man. Neither is this the first time

Digitized by Google

hat Sir LYON has disappointed the profession. Ten years ago, when Mr. GLADSTONE'S Government brought in a Bill, he could have carried direct representation with a little pains. But he did not take the pains, and the Bill was lost. Now he has had the courage to move the omission of the other great principle, the reduction and consolidation of the licensing authorities; and by so harassing the Government, which too easily yielded to his pressure, he has wrecked another Bill. Few men had it in their power to do so much good or so much harm. He has chosen to do harm and to wreck another Medical Bill. The Edinburgh University and Sir LYON PLAYFAIR doubtless know their own business best, but the profession will not soon be convinced that Sir LYON PLAYFAIR has any claim to its confidence, seeing that he has on two great occasions so blighted its most reasonable and most ardent hopes.

IT is not for us to rejoice in the adverse issue of an action at law arising out of proceedings that discredit the profession to which we belong, and which it is our pride to represent. At the same time, it must be confessed, we believe good—great and lasting good—will come out of this evil. The men upon whom the Tower of Siloam fell were not worse than a multitude of others who were not so visited; but it was none the less on that account a fact that wrong-doing merited punishment. We have for many years past protested, in the name of the profession, against the lunacy laws and the system of private asylums. These laws are as bad as they can well be, and the pretended supervision exercised by the Commissioners in Lunacy is a farce, a technical travesty of protection, nothing better, and, on the whole, tending to increase the peril of evil by throwing a false glamour of security over them. So far as the relations of the public to the medical profession are concerned, the whole principle of the law of lunacy is utterly and hopelessly wrong, and places us in a false position. The power of imprisonment given to the keepers of asylums, whether public or private, is not needed. The manner of proceeding by examination and certificates is clumsy and ineffective. The endowment of "medical" certificates with the power of a *lettre de cachet* is a violation of the underlying principles of law and justice, and outrageously and recklessly imprudent. The reception of such certificates from any and every member of the profession without regard to special qualification of any sort is an astounding piece of stupidity. And the attachment of any value whatever to the scrutiny of these certificates by the Commissioners must be perfectly inexplicable to anyone who knows anything of the facts. The Commissioners do not even go through the farce of inquiring into the nature of the case, the accuracy of the allegations made, or the *bona fides* of the persons making them. The keeper of the asylum is the only person who has any check on the medical certificates given outside, in the sense of judging whether the statements made in those documents are true or false; and, in the case of the keeper of private asylums at least, this person is directly interested in the retention of the patient placed under his care. It is an unjustifiable and misleading pretence on the part of the Commissioners that they exercise any protective control over the certificates. This is perfectly well known at Whitehall; and we cannot understand how it comes to pass that it has not been avowed, in the House of Lords at least, that the Commissioners cannot possibly do more than look to the clerical fulfilment of technicalities in regard to the way in which the forms are filled up. As regards the private asylum system, there is nothing to add to what we have already said on the subject—namely, that it is wholly antagonistic to the interests of public safety. Meanwhile, we think the time has come when the medical profession should clear itself from the discredit of being connected with such a system, and when the College of Physicians, which forbids its members to enter into professional partnerships, should set its face also against this trade in lodging-houses for lunatics. The election of members who are engaged in this lodging-house-keeping to the Fellowship of the College is an enigma we have never been able to solve.

We do not wish to sit in judgment on the particular case which has just been decided, so far as the medical men are concerned. The manner in which the procuring of certificates in this case was carried out, and the manner in which the supposed lunatic was examined and the forms were filled up, do not strike us as being either better or worse than the methods of procedure adopted by men more eminent than those engaged. We do not think any member of the profession engaged in lunacy practice has a right to cast a stone at those of his brethren who have been in this instance "found out." The eminent specialist who leans his arm on a mantelshelf and asks a few questions on general topics without taking any step to ascertain the physical state of his patient, albeit and paradoxically the distinguished physician may not believe in the existence of anything outside the organism, and may regard mind as brain-function, and nothing more; and the eminent specialist who spends two hours in the discussion of a question of spiritualism with the patient he is examining, are not in a position to complain of the manner in which the medical men concerned in the recent case discharged their "duty." It matters little how an essentially bad thing is done. We have no hesitation in affirming that, except in cases where the certificate is needless because the case is plain to everybody, an opinion formed at a single interview must be untrustworthy. Of course there are cases of brain and nerve disease, such as general paralysis of the insane, brain-softening, and the like, on which a rational diagnosis may be made, but these are cases which the profession generally understands. We do not deny that special study of the pathology of the nervous system as a whole, or of the brain in particular, may enable a physician to recognise cerebral disease by the abnormalities of cerebral function. This is a distinctly scientific position to take up. Meanwhile we do deny that a knowledge of medicine in the broad sense renders it possible to recognise mental disease, or to discriminate between eccentricities and delusions without the application of precise scientific tests. The members of our profession who have been assailed in this case have our sympathy, not because we entertain the smallest doubt that what they did was unwise, and in that sense wrong; but because we fail to see that they have done anything worse than is done daily by more eminent men around them, and that will and must

Digitized by Google

continue to be done until the law is altered, and the scandal of the lunacy system as a whole permanently effaced.

THE subject chosen by Dr. MILLER ORD for his Address in Medicine, delivered this week at Belfast before the British Medical Association, is one which illustrates in a striking manner the tendency of modern thought towards a neurotic system of pathology—not, indeed, in the old sense of the predominant influence of nerve action throughout the whole range of disease, but yet ample enough to prevent its full exposition in the limits of a lengthy and closely reasoned address, abounding in clinical facts. The address will do much to attract attention to this interesting and fertile field, which has been explored already on so many sides, and in which Dr. ORD himself has done much to elucidate the inter-relations of morbid states. No one can doubt in the present day the very close and direct connexion subsisting between the processes of nutrition and secretion and the nervous system. Examples of such a connexion are daily before us, and new instances are being constantly brought to light. Often the knowledge depends more upon inferences derived from the clinical course of diseases than of such positive proof as the morbid anatomist or the physiologist would demand. But the examples are now so numerous, and those in which obvious nerve lesions are present are so similar to those in which such changes are wanting, that there is little room for escape from the conclusions arrived at.

Prominent among such disorders of nutrition, or, as Dr. ORD terms them, "neurotic dystrophies," are affections of the muscles and joints, and the first alluded to in the address was muscular atrophy dependent upon articular disease. It has been observed that such wasting may occur out of all proportion to the disuse of the limb, and a well-marked instance was quoted from M. CHARCOT of atrophy of the vasti muscles in a case of traumatic arthritis of the knee. M. CHARCOT—whose name is inseparably associated with this subject—explained the muscular condition in that case by the transmission of nerve influence from the diseased joint to the spinal cord, which operated upon the centres governing the nutrition of the muscles connected with the joint—an argument which receives support in the occurrence (in a case recorded by RUMPF) of an arthritis of the knee, set up after fracture of the thigh apart from any continuity of the inflammatory process. From these comparatively simple instances of trophic disorder in limbs, excited through the action of the spinal cord, Dr. ORD passed to consider the wider question of similar lesions being produced by central disease or by nerve irritation from sources other than parts of the limbs. The similarity of the joint affection in tabes to the lesions of chronic rheumatic arthritis—a similarity that has led many to be sceptical as to the propriety of separating "tabetic arthropathy" from the more general affection—is suggestive of a common bond in nerve disorder. The connexion of muscular atrophy with affection of the anterior cornua of the cord is well established; and very interesting is the observation made by Dr. GULLIVER of a case of progressive muscular atrophy complicated with a painful affection of the shoulder. Pointing in the same direction is the muscular wasting and other dystrophic phenomena associated with chronic joint disease, and especially chronic rheumatic arthritis, a condition of muscles which bears very marked resemblance to that of progressive muscular atrophy. Nor do these clinical facts by any means exhaust the catalogue of conditions which suggest more than has yet been capable of proof. Thus, Dr. ORD related the details of a case of severe and painful progressive rheumatic arthritis, which was initiated by a chill, affecting particularly the spinal cord. SENATOR, indeed, argues strongly for the nervous origin of rheumatic arthritis, and appeals to the symmetrical distribution of its lesions in support of the view, an argument which, as Dr. ORD points out, was so forcibly used by Sir JAMES PAGET as affording evidence of a blood disease.

The considerations thus advanced, which all point to the direct interference of the nervous system with the nutrition of the limbs and their articulations, were turned to excellent account by Dr. ORD in dealing with the chief subject of his address—a subject which, it may be remembered, he brought before the Clinical Society of London a few years ago. His contention is that the nodular form of chronic rheumatic arthritis (digitorum nodi of HEBERDEN) is intimately associated with uterine irritation. And the abundance of clinical facts advanced in support of this argument goes far to justify it. For not only is the affection far more common among women, but it is closely connected with dysmenorrhœa and other symptoms of disordered uterine function; whilst in several of the cases detailed by Dr. ORD relief from the joint disease was not obtained until the climacteric was reached. This association has been pointed out by others, but hitherto it has generally been considered that the connexion depended upon an altered blood state rather than on nervous influence. Thus once more we seem to be confronted with the well-worn controversy between humoral and neuristic pathologists. When, however, we consider all the allied facts which Dr. ORD has marshalled, it does not seem so irrational to invoke the agency of the nervous system to explain these striking disorders of nutrition. At least it may be conceded that the humoral view is quite as open to criticism, and in point of fact less capable of explanation. Dr. ORD, however, is not contented with this; and fully confident of the security of his own position, he advances still further against the humoralists, claiming gonorrhœal rheumatism to be a neurotic disorder. In so doing he has pushed the doctrine he advocates almost beyond due limits; and yet for those who admit the truth of the previous reasoning, it is not difficult to follow him here. Certainly it is curious that gonorrhœa in women is seldom (Dr. ORD seemed to say "never") associated with rheumatism, as it is in the other sex; but for all that few will, without further evidence, adopt the doctrine laid down at Belfast, that the relatively great excitability of the prostatic part of the urethra (*quoad* the spinal cord) accounts for the supervention of arthritis in cases of gonorrhœa or urethritis. Naturally the mind reverts to examples of "urinary paraplegia," and Dr. ORD did well to adduce them in support of his views.

It would, we venture to think, have been better had the address ended here. It had arrived at a climax of no small importance, and up to this point doubtless it fully engaged the attention of the audience. We can imagine that they

Digitized by Google

would have been contented with this, having received sufficient material for thought and contemplation. So it was rather hard upon his hearers for Dr. ORD to have started off anew to consider the subjects of glycosuria and its relation to nerve influence, the mechanism of the occurrence of intercurrent inflammation in diabetes, and the nervous relations of myxœdema, full of interest as these subjects are. There can be no question as to the interest of the address, nor as to the wealth of clinical material whereby it was illustrated; whilst many will be grateful to Dr. ORD for having chosen a definite subject in preference to dealing in generalities; in pointing the paths open to inquiry rather than staying to admire what has been already achieved; thereby making a really useful contribution to medicine, and one worthy of the occasion on which it was delivered.

IN view of the increasing tendency to treat pelvic disease by abdominal section, any trustworthy statistics are valuable. In the case of cancer of the cervix uteri, the frequency of the disease makes the question of treatment one of ever-persistent importance. A contribution of great value bearing on this matter has lately been added to our knowledge by PAWLIK, who gives us careful records of 136 cases treated by the galvanic cautery in the first gynæcological clinic of Vienna, and kept as far as possible under observation from the date of operation. When we mention the fact that the cases extend back to the year 1861, the importance of PAWLIK'S report will at once be perceived.

The mode of operation adopted has been that of the galvano-caustic wire, which (in spite of an apparently theoretical preference for cutting instruments) has been found to furnish the best results. The details of the operation are given at length, and comprise the principles of getting, if possible, beyond the disease, and performing the amputation through healthy tissues. This is effected by seizing the cervix or vaginal wall (if encroached upon) with the volsella forceps and sharp hook, taking care that the loop lies beyond them. A caution is given to tighten the loop very slowly, especially in cutting through the periphery, in order to prevent bleeding; and to avoid making a premature circuit by allowing both wires to touch the steel instruments, by which accident the écraseur becomes simply a cutting instead of a burning instrument. If it is acting well, a seething noise can be heard on auscultating above the pubes. The part removed is examined to see whether (*a*) the peritoneum has been opened, and (*b*) the disease has been entirely removed. The peritoneum contrasts with the charred surface by its cartilaginous glistening. Imperfect removal of the disease is seen by the cut section not appearing homogeneous, but lighter in colour and exuberant. The peritoneal wound is generally of little moment. The imperfect removal of the disease must be supplemented by the scissors, galvanic cautery, or thermo-cautery. The slough generally separates on the tenth to the fourteenth day, by which time the peritoneal wound (if present) is generally healed. The granulating surface is then stimulated from time to time by lunar caustic. There is nearly always cicatricial narrowing or even closure of the canal, sometimes producing considerable menstrual retention. To avoid this the sound should be frequently passed. The author also adds that pregnancy, which under the circumstances is disastrous, is thus abolished. Patients rarely obey orders to attend regularly, and therefore complete closure is infrequent. In this case the canal has to be opened or manufactured, by trocar, knife, or metrotome. After incision nothing should be done for three weeks, lest peritonitis &c. supervene; and then the sound should be passed in order to break down any adhesions which may have formed.

The results obtained by PAWLIK are as follows:—Patients who died in hospital, 10; of these, 1 died from recurrence of the disease nearly four months after the operation, 1 from marasmus twenty-five days after, 8 shortly after (3 from anæmia, and 1 from peritonitis). Patients lost sight of, 22; of these, however, 2 were known to be in good health two years after the operation. Patients who left the hospital not cured, 16. Patients who died outside the hospital, 31; of these, 16 died probably from recurrence (1 three years after the operation), 1 had a return *near* the uterus two years after the operation, the cicatrix being unaffected, and 3 died of tuberculosis. Cases which relapsed, 22 (date of death unknown); among these, 1 patient remained in good health for six years, 1 for nineteen months, and 2 had cancer outside the uterus, the cicatrix remaining intact. Patients who died in childbed without recurrence, 2; one in seven years and a half, the other one year later. Those who remained in good health numbered 33—viz., nineteen years and a half after operation, 1 (seen in good health nearly twenty-one years after operation); twelve years after, 2; eight years after, 3; seven years after, 3; five years after, 3; four years after, 2; three years after, 5; two years after, 7; and one year after, 7. With regard to the very important question of the correct diagnosis of malignant disease, a microscopical examination is expressly reported in the following cases, which remained healthy: 1 nearly twenty-one years, 3 twelve years, 5 ten years, 6 eight years, 12 six years, 18 three years, 19 four years, 29 two years, and 33 one year, after the operation. The peritoneal cavity was opened thirty-nine times behind, and once both in front and behind; of these patients, 4 died—2 of anæmia and 2 of peritonitis. Hæmorrhage occurred during or immediately after the operation six times; in 5 cases it was checked by styptic cotton, and once by the cautery. Secondary hæmorrhage occurred in 13 cases; once on the eighth day, twice on the ninth, and once on the tenth, eleventh, twelfth, thirteenth, and seventeenth days. Vesico-vaginal fistula occurred on separation of the slough three times; in one instance this was due to rapid return of the disease, which had been imperfectly removed. Parametritis only occurred once.

The matter is so important that the foregoing facts ought to be known. The disease is manifestly localised, and not general, in many cases, and a hope of cure is therefore not to be absolutely denied. Necropsies have shown thickening in the neighbourhood of the growth to be sometimes purely the result of inflammation, and not of malignant infiltration. The operation for extirpation of the uterus by abdominal incision is most difficult, unsatisfactory, and perilous; the vaginal operation, though generally preferable, is not much more satisfactory; and the ultimate results of cases of extirpation of the uterus for cancer show that even this operation by no means ensures against return of the disease. Practice with regard to the affection seems to have sepa-

Digitized by Google

rated itself into two widely divergent lines: on the one hand, to remove the disease only in those cases in which a protuberant mass presents itself; and, on the other, to treat the disease by extirpation of the whole organ. The latter appears to be an unnecessary operation in many cases, the disease having a frequent tendency to extend laterally instead of vertically. The former implies the abandonment of some women whom a more hopeful view might have helped to cure, and very many of whom might have been relieved. Even where the uterus is fixed, an operation sometimes produces happy results. A woman, for instance, may have fever, sweating, and all the symptoms of septic intoxication; the disease is partly (and, it is true, imperfectly) removed, the symptoms instantly subside, and she enjoys a period of what seems to her perfect health. The result of PAWLIK'S statistics will probably be that we shall hear less of extirpation of the uterus and more of removal of the cancerous cervix.

THE address on Physiology, delivered at the Belfast meeting by Professor REDFERN, deals chiefly with the broad general truths of physiology, and is an endeavour to trace the recent advances in histology and in physiological pathology and their application to medicine and surgery. The subject is a difficult one, but the Professor exhibits a large and varied knowledge of modern work, and with this object in view he cites numerous observations and experiments. He cordially agrees with the doctrine explicitly laid down by Professor HUXLEY, in his Presidential Address to the British Association for the Advancement of Science, that all living matter has been derived from previously living matter of its own kind, and that all living beings and living tissues have originated from fragments of previously living beings or tissues, which, when detached, carried the properties of their parents with them. He shows how living matter presents alterations proceeding both from inherited predisposition and from the action of external changes, and he dwells in particular on the relations that exist between the blood and the tissues and the influence of agents affecting the tone and vital properties of the vessels. To illustrate his statements, he adduces the observations of WILLIAMS, who showed the effects of applying solutions of capsicum to the web of the foot of the frog; the experiments of LISTER, who demonstrated the delicacy of the relations between the walls of the bloodvessels and the circulating fluid; those of CONHEIM, who described the effects on the diapedesis of white corpuscles in arresting the circulation through certain vessels for two or three days; and those of RANVIER, who himself citing the remarkable phenomenon of the migration of white corpuscles into pieces of dead membrane inserted into the peritoneal cavity, and the difficulty of maintaining that the migration of corpuscles is in such instances due to an increased attraction between them and the tissues, arrives at the conclusion that we are returning to the notion of JOHN HUNTER, who accounted for the inflammatory blush by referring it to the action of the vessels. But important as the vessels are in bringing pabulum to the tissues, in the active discharge of their function, they still hold a secondary position as compared with those more intimate relations which exist between the blood and the tissues themselves. "Here," as the Professor observes, "is the real laboratory of the system; the place where the work of the body is done." The vessels, indeed, supply a larger or smaller quantity of the fluid plasma, in which all the tissues are bathed, in proportion as their demands are greater or less at one time than at another; but it is the business of each tissue to select, both as to character and amount, all it requires, and the energy with which this is effected is well shown by the high pressure at which the cells of the salivary gland excrete saliva.

In order further to elucidate the deeper relations existing between living and non-living matter, and the processes by which growth and nutrition are effected, the Professor next proceeds to consider the anatomical relations of the tissue elements to the lymph spaces, and to the contents of the lymph spaces, and lightly sketches the histological observations of v. RECKLINGHAUSEN, KLEIN, and others—showing that such spaces are far more widely distributed through the body than was formerly imagined; additional proofs of the important part they play in the economy being obtained by the immediate effect of endermic injections, now so familiar to all practitioners. The rapid absorption—a process that has indeed been actually witnessed—of milk and other fluids from the peritoneum, and the mode in which, if CREIGHTON'S observations are correct, the chyle is taken up from the intestines, the cells themselves forming the epithelium of the lymphatic spaces, or at least being immediately continuous with these spaces, and constituting the agents of absorption. The contents of the lymphatics are composed of plasma and corpuscles, and the mode of origin of the corpuscles has a special interest, since it affords some clue to the manner in which the blood-corpuscles are constantly being renewed and large losses of blood are repaired; and the organs in which the lymphoid cells are produced have been shown by recent research to be extraordinarily great, for, in addition to the lymphatic glands, the spleen, the adenoid tissue of the intestines and mucous membranes generally, the cancellous tissue of bones and many other parts, are all engaged in the production of leucocytes, the destination of which, obscure as the intermediate stages are, seems to be the renovation of the blood. From the lymphatic system Professor REDFERN travels by an easy transition to the domain of pathology. He refers to Sir JAMES PAGET'S investigations into the processes of repair, to the observations of ZIEGLER on the mode of recovery from burns, to the communication of syphilis by inoculation, and to what he rightly terms the most difficult, exciting, and important problem of the day—whether other diseases than small-pox can be deprived of their virulence by vaccination. If PASTEUR'S hopes in this respect are verified, it may perhaps be the glory of some future period to render even hydrophobia innocuous. In the meanwhile, investigations of this kind are left to the ardour of private individuals; and in this country, at least, Professor Redfern laments, little aid is afforded by the public, who, in the mischievous legislation of the few last years, are opposing the efforts of those whose labours would prove of the greatest possible benefit to them.

A SELECT COMMITTEE is to be appointed next session to inquire into the subject of the multiplication of overhead telegraph wires in the metropolis.

Annotations.

"Ne quid nimis."

THE HEALTH OF PARIS.

DURING the recent discussion in the French Chamber on the sanitary condition of France, M. Paul Bert described France as being, next to Spain and Turkey, the most backward European country in sanitary matters. With especial reference to the health of Paris, he stated that the deaths in that city exceeded by 8000 per annum the number returned in London, after allowance for the different populations of the two cities. It is much to be regretted that the Chamber rejected the proposal for the appointment of a committee on sanitation, more especially as M. Bert's figures very much understated the excess of mortality in Paris compared with that in London. The annual death-rate in Paris during the five years 1879–83 averaged 27·1 per 1000, while the annual rate in London during the same period did not exceed 21·4 per 1000. To make these rates strictly comparable, however, it is necessary to take into account the relative age constitution of the populations of these two cities. The proportion of children aged under five years in Paris is scarcely more than half that in London, and this difference is but slightly compensated by a small excess in the proportion of the Paris population aged upwards of sixty years. Indeed, the age distribution of the Paris population is so favourable to its death-rate, that by applying the English life-table rates of mortality to each of five groups of ages its normal death-rate is found to be only 19·92 per 1000; whereas the normal death-rate of the London population obtained in a similar manner is 21·79. As the *normal* death-rate in London is 9·8 per cent. higher than that of Paris, it is necessary to raise the recorded death-rate in Paris by 9·8 per cent. for difference of age distribution, in order to make it fairly comparable with the recorded rate in London. The Paris annual death-rate for the five years ending 1883, thus corrected, becomes 29·8, which is 8·4 per 1000 above the London rate for the same period. The true excess of mortality in Paris, compared with that in London, is therefore more than double that stated by M. Paul Bert, and urgently calls for a thorough reform in the sanitary organisation of the French capital. In 1883 alone more than 2000 deaths from typhoid fever were recorded in Paris, which, although showing a marked decline from the still larger number in 1882, were equal to a rate nearly four times greater than the rate from the same disease in London. It may be hoped that the force of public opinion in Paris may induce the French Government to adopt some measure similar to that which was last week supported by M. Bert, and was only defeated in the Chamber by 219 votes to 193.

SIR WILLIAM MAC CORMAC'S ADDRESS ON SURGERY.

THE executive of the British Medical Association decided that there should not be any special Association Address in Surgery this year, and we therefore turn to the address delivered by Sir William Mac Cormac as President of the Surgical Section as the leading contribution to this branch of science at this meeting. Sir William Mac Cormac chose not to dwell on any of the special scientific problems now exciting the interest and thought of surgeons, but preferred rather to detail certain operative successes of his own. He first related two cases of gastrostomy for malignant disease of the œsophagus, in which he was enabled to postpone the second step of the operation in the one case for fourteen days, and in the other for seven weeks. In his remarks upon these cases he urges the importance of resorting to the operation early, so that the surgeon has sufficient time to secure the firm adhesion of the stomach to the parietes before it is necessary to open the stomach. This caution was, however, carried too far in his second case, for there is no practical advantage in allowing seven weeks to intervene between the two steps, and this patient was obviously operated upon five weeks too soon. Sir William Mac Cormac then detailed sixteen cases of radical cure of hernia performed either primarily or as a sequel to the relief of strangulation of the bowel. Of these, thirteen were quite successful. The method adopted was to excise the sac and ligature its neck with, in some cases, suture of the ring or rings, although Sir William does not place much value upon the latter step. This series of cases is very good, and they will, no doubt, help surgeons generally in adopting the practice which has been advocated and practised by some few, of converting all operations performed for the relief of strangulated hernia into the radical cure of the affection. The last case recorded is one of excision of a large goitre. There were no special features in this case beyond the large size of the tumour, its great vascularity, and the consequent difficulty and long duration of the operation. Sir William is evidently of opinion that the fear of inducing the cachexia strumipriva must not be allowed to prevent surgeons interfering in otherwise suitable cases, and he thinks that this sequela is only to be expected when the operation is performed upon children or adolescents.

BEER-DRINKING AND HEART DISEASE.

THE most essential factors of the living heart are unquestionably its neural and muscular elements. It may seem superfluous to assert so plain a truth; nevertheless, the necessity of bearing this fact in mind is demonstrated by every-day experience. If the heart be the subject of debate amongst medical students at our hospitals, how much do we hear of the murmurs and how little of the condition of the myocardium! Our present object is to draw attention to a class of cases which have not received the wide study they deserve. Idiopathic hypertrophy and dilatation of the heart are not phrases which carry their own credentials. To speak openly, the term "idiopathic" is regarded by scientific physicians as a pleonastic cloak for our ignorance. Cardiac hypertrophy of idiopathic sort is said to be of common occurrence in Munich as compared with other cities. Spatz found that of 638 men no less than 35 were affected with so-called myocarditis. Among 433 women there were 23 cases. Of 290 men between the ages of thirty and sixty, there were 41 cases of myocarditis, or about 14 per cent. Of 144 women at the same period of life, only 10, or about 7 per cent., were affected. Hermann's reports showed 49 cases of muscular disease of the heart in the male among 305 necropsies, whilst only 3 females had this condition. Von Buhl looked on these instances of cardiac hypertrophy as the result of chronic myocarditis, which usually ended fatally in consequence of fatty degeneration of the muscle. Bollinger, who has restudied this subject, cannot find any evidence of inflammatory changes or fatty degeneration. At his suggestion, Schmidebauer undertook to establish the extent of the prevalence of cardiac hypertrophy in Munich upon a statistical basis, with a view to making clear its causation. Among 1000 necropsies there were 46 cases (32 men and 14 women) in which the cause of death was attributed to simple hypertrophy of the heart. As an associated condition, not as a cause of death, idiopathic hypertrophy of the heart was found in 33 other cases (23 men and 10 women). All cases of enlargement of the heart due to lesions of the valves, or disturbances of the pulmonary circulation, or associated with arterial sclerosis, or granular kidneys, were said to be excluded. Some of the cases were attributed to prolonged muscular effort. But the greater number were believed to be due to habitual excess in beer drinking, attended with a

Digitized by Google

true plethora or overcharge of blood. It is argued that the habitual consumption of beer in large quantities tends to enlarge the heart by the direct action of the alcohol on its tissues, by the increase in the amount of fluids in the body, and by the belief that the nutritive ingredients of the beer are easily assimilated. Statements are made to the effect that the average weight of the heart in men is relatively greater in Munich than elsewhere. Both sides of the heart participate in this hypertrophy. It may naturally be asked how it is that sufferers from simple hypertrophy are prone to die of an affection which apparently contains no fatal elements in its composition. The phrase simple or idiopathic hypertrophy is in this respect misleading. Exhaustion of the nervous apparatus without obvious disease of the muscular tissues is the proffered explanation of the fatal result—an explanation not altogether free from valid objections. As an interesting fact it may be stated that during the year 1882 the average amount of beer consumed by each person in Germany ranged, in different districts, from 54 to 186 litres, in Bavaria it reached 233 litres, and in Munich 432.

SCHOOL PRESSURE AT THE HEALTH EXHIBITION.

If nothing essentially new was elicited at the discussion on School Hygiene on Tuesday, the views of those who believe that education is taking unhealthy and unnatural forms were stated with new force and clearness. Mr. Teale's paper, in particular, was a bold and clear indictment of the existing system, with its ever-multiplying examinations, its premium on cram and cleverness, and its want of respect for good, general, and sensible results. Mr. R. Brudenell Carter was equally explicit in saying that the present system was injuring the eyesight. Defects of sight were increasing, and in one board school in London, he said, no less than one-fourth of the children were suffering from such defects. A word was said by Mr. C. E. Shelley, M.B., in defence of old-fashioned methods of corporal punishment, "which modern sentimentalism seemed inclined to abolish altogether," but which, by the way, are not altogether extinct. Sir Joseph Fayrer wound up by pointing out the evil results of children having to prepare lessons at home in the evening. The fact is that we ought to make education more pleasant, healthy, and natural, and should remember that the world does not exist for clever children, but for ordinary ones. The success of our methods should consist in turning out the largest number of healthy, happy, and capable pupils, not in creating a few prodigies.

THE CHOLERA GERM AND ITS DISCOVERER.

OUR correspondent in Rome writes:—Professor Filippo Pacini of Florence, the discoverer of the tactile corpuscles which bear his name, contributed in 1854 to the *Gazzetta Medica Italiana* a paper on the cholera visitation, in which occur the following words:—"Esaminando minutamente le diverse parti del tubo gastro-enterico dei colerosi morti nello stato algido, dovei convincermi che quella lesione epiteliale non è operta da altri che da *un organismo semplicissimo e di estrema tenuità, che io appellerò microbio* con termine generico e moderno e specialmente *microbio colerigeno*." (Examining minutely the different parts of the gastro-enteric tube of subjects dead from cholera when in the algid state, I was forced to the conviction that that epithelial lesion is caused by nothing but a very simple organism of extreme tenuity, which I shall call "microbe," a term generic and modern, and with special reference to the disease in question, "cholerigenous microbe.") As usual, this pregnant discovery was more quickly and thoroughly appreciated by foreigners than by its author's own countrymen, and in 1865, on the next cholera visitation, Pacini wrote:—"Quando i miei lavora scientifici dall' Europa saranno tornati a Firenze abbigliati alla foggia straniera, potranno avere il permesso di entrare nelle scuole e allora noi saremo nel placido riposo di Trespiano." (When my scientific labours, having made the tour of Europe, will have returned, arrayed in foreign garb, to Florence, they will have permission to enter the schools, and then we shall be enjoying the tranquil repose of Trespiano—in our grave, in short.) This bitter forecast has been verified almost to the letter, Pacini's doctrine, rehabilitated by the German Cholera Commission, being now adopted by his compatriots and taught in the Istituti Pathologici of Italy a year after his death.

SMALL-POX AT THE DIAMOND FIELDS.

FROM the *Port Elizabeth Telegraph* of June 28th we learn that at that time small-pox was spreading with alarming rapidity at the Diamond Fields. There were over 300 cases at Dutoitspan. The lazaretto accommodation was unequal to the demand upon it, and persons stricken with the disease had to remain outside. The virulence of the epidemic showed no signs of abatement as to mortality, for, according to Dr. Sauer, the death-rate was 25 per cent. The time has surely come for the most vigorous attempts to free the colony from this deadly plague. We trust that the medical men who have so persistently refused to accept the opinion of the bulk of the profession will now see their way to acknowledge the inaccuracy of their diagnosis, and generously aid the authorities in their attempts to stem the torrent which threatens to swamp the community. If we mistake not, Kimberley and the adjoining districts will have enough, and more than enough, to do to cope successfully with an epidemic that heeds neither the caprice of fortune nor the folly of indifference. It seems incredible that the Government should not ere this have awakened to a sense of the enormous responsibility cast upon it. If the local authorities are powerless to meet the exigencies of the case, it is surely time for the central executive to step in and not only indicate the course of action, but provide also the means of carrying their recommendations into effect.

LEFT HEMIPLEGIA AND APHASIA IN A RIGHT-HANDED PATIENT.

CASES of left hemiplegia and aphasia in which the patient was not left-handed possess considerable interest to cerebral physiologists. M. Michel Catsaras has recorded an instance of this combination of facts in *La France Médicale* of July 17th. The patient was a Greek, aged thirty-five years, a broker by profession, and enjoyed good health till August, 1883, when his wife noticed that his mouth was drawn to the right. At this time there was no other symptom of disease. The facial palsy is said to have passed away in a fortnight without treatment. At the end of September, whilst in a café, the man was seized with a fit, fell down unconscious, and remained in this condition for half an hour, at the end of which time he came to, and it was discovered that the left side was paralysed and the faculty of speech was gone, with the exception of the words meaning water and bread. To every question asked he replied νερο and ψωμι. He understood everything that was said to him or what he read, and could write perfectly what he thought. After fourteen days the hemiplegia and aphasia had so much passed away that he was able to go to work again. According to his wife, however, he did not please his clients. During the month of November the patient suffered much from nausea, thirst, and hunger. On January 20th, 1884, a fresh attack of unconsciousness set in, which was followed by profound aphasia and left hemiplegia; he could neither speak,

Digitized by Google

write, read, nor understand much that was said to him. M. Catsaras diagnosed thrombosis of the right Sylvian artery. The case does not seem to have been followed by an autopsy. The author thinks the notion of lesions in the two hemispheres not tenable, and suggests that in this case the pyramidal tracts did not cross at all. Dr. Hughlings Jackson described a case of aphasia with left hemiplegia in a right-handed person in THE LANCET of April 24th, 1880.

THE PRESIDENT'S ADDRESS AT THE BRITISH MEDICAL ASSOCIATION.

THE presidential address with which Dr. James Cuming opened the fifty-second annual meeting of the British Medical Association, held this week at Belfast, was a dignified and scholarly production. Wisely refraining from dwelling upon the topics of local interest that so often form the staple of these utterances, Dr. Cuming dealt mainly with the most pressing questions of the medical science of to-day, and did good service in drawing attention to the directions in which the profession should work to advance the knowledge of disease and the power to cope with it successfully. He did well to remind us that apart from the valuable researches which now engage so much attention, and which tend so much to show that the ancient doctrine of disease being in the main the result of external agencies is not far from the truth, there are great questions to be solved respecting racial proclivities and individual tendencies which are open for inquiry by the collective research of all practitioners. For important as is the knowledge gained from the study of the part played in etiology by the numberless forms of micro-organisms that have been revealed to us by the patient research of the pathologist, and valuable as such knowledge may come to be in showing us how to prevent and cure specific diseases, it would be folly to lose sight of the larger facts that need no microscope for their detection. Another warning, not less needed, was given in this address, to the effect that anatomical investigations should not be allowed to eclipse the facts gained by clinical observation. It was this which Trousseau feared, and against which he used to declaim, perhaps with too much bias; and it was happily illustrated by Dr. Cuming in the much-debated subject of scrofula and tubercle. The morbid anatomist declares for an identity, while the clinical observer sees nothing more than a kinship; and he is the true pathologist who, taking into account the morbid condition as observed in the living patient, applies that knowledge to explain the changes that dissection and microscopical investigation reveal to him. In a like spirit Dr. Cuming adverted to the advances that are being made in pharmacology and therapeutics, and he maintained that the scientific pursuit of medicine is not to be shackled by the methods followed in physical science, whilst adhering to the general principles that govern all scientific research.

UNRIPE AND UNSOUND FRUIT.

AFTER so many former warnings as to the close connexion between unripe or too ripe fruit and disease, it may be doubted whether further remarks will convey any fresh information on the subject. The advance of cholera on the Continent gives a new and important interest to all such observations, since no better conditions for the spread of that disease can exist than such as are furnished by the presence in the market and the household of unsound fruit. It is true that legislative interference with a subject of this kind might be overdone, and is but little needed on behalf of the better educated and wealthier classes, for with them unsuitable fruit does not find much acceptance. The poorer population, on the other hand, have much greater difficulty in selection. Their fare must be cheap, and cheapness in regard to fruit signifies—though it need not and should not—unripeness, over-ripeness, or damage, far more often than mere poorness of quality. In their interest some legal control over fruit-sellers is necessary, and no doubt is already exercised in glaring cases. A greater degree of stringency, however, is called for, and would not be oppressive. Supervision, in order to be effective, should be rigidly enforced at the central markets, and also to some extent at the stalls of street vendors.

PROFESSOR DE CHAUMONT ON DISINFECTANTS.

NOT the least valuable part of Professor De Chaumont's lecture at the Health Exhibition on cholera and its prevention was that in which he exposed the untrustworthiness of many so-called disinfectants. The belief in a few of these disinfectants has come to be almost a superstition, and it has been too much played upon by some sanitary authorities, and even medical officers of health, who in times of small-pox have covered all available hoardings in the parish with posters vaunting the epidemic virtues of disinfectants. Professor De Chaumont said: "In regard to disinfectants, there is but one true disinfectant—viz., fire. The majority of so-called disinfectants are simply deodorants. The idea that tobacco smoke or the odour of camphor is destructive of contagion is still extensively held, though it is simply absurd. A true disinfectant is a substance that will kill the germ or living particle in which the contagious principle resides, or through which it is conveyed." Of true disinfectants, as Professor De Chaumont says, undoubtedly heat is the most reliable, though others are not to be despised, such as carbolic acid, chlorine, and sulphurous acid gas.

MEANS OF ISOLATION AT LIVERPOOL.

THE question of the erection of a hospital for infectious diseases for Liverpool has entered on its most difficult stage. No site can be suggested without at once raising the problem of the extent to which small-pox patients may be aggregated together without danger to the surrounding community. The present proposal evidently relates to a large hospital which shall endeavour to cope with the existing epidemic, and to such a hospital in the vicinity of Wavertree-park objection is taken by an important section of the public and of the press. We have already expressed an opinion against the aggregation of cases of small-pox in large numbers; we have advocated the establishment of several hospitals instead of one in the case of populous places like Liverpool; and everything that takes place in connexion with this subject goes to confirm us in these opinions. The Hospitals Commission evidently held the same view when they urged that no small-pox hospital in the metropolis should be capable of receiving more than some forty acute cases, and the Fulham experience, on which this recommendation was based, was conclusive in the same direction. Whilst we cannot but sympathise with the corporation in their attempt to overcome the difficulties which face them in the almost impossible task of dealing with an existing epidemic by measures of isolation, yet we feel that their opponents have just grounds for their suspicions of possible mischief. The attempt to deal in an emergency with an epidemic which has already widely diffused itself is by no means promising, and it is already surmised that the temporary sheds advocated cannot be ready in time. If the Liverpool corporation were to take advantage of the present crisis to secure several sites, at each of which some permanent buildings could be erected which would serve for the isolation of the several infectious fevers, the opposition which they are meeting with might subside, and they would then be prepared to cope with other diseases as well as small-pox; whereas, so

Digitized by Google

far as our experience goes, extensive small-pox sheds never serve for the isolation of other diseases, and they tend, by the aggregation of the most tenacious of all infections, to produce the very evil which they profess to obviate. Indeed, according to local information, Liverpool itself affords one of the most recent proofs of this result.

DIPHTHERIA AT BIERTON.

AN interesting report on a recent outbreak of diphtheria at Bierton has been issued by Dr. R. H. Hilliard, medical officer of health to the Aylesbury Rural District. Some were well-marked cases, with characteristic symptoms and sequelæ, others were mild and of an indefinite type, and others, again, were regarded as scarlet fever, one of these latter, however, being followed by paralysis of the soft palate. The disease would appear to have been imported by means of a convalescent who had had an ill-defined attack and to have had its spread facilitated both by the bad sanitary state of the house into which the case was received and by intercommunication between the healthy and the sick. Dr. Hilliard points out that, according to recent researches, two kinds of organisms are associated with diphtheria:—1st, the ordinary diphtheritic germ, which is easily destructible; and, 2nd, "resting spores" or germs, which are absorbed into the blood during the course of the disease. These "resting spores" can live under more unfavourable conditions than the other germs, and they resist destruction much more easily, continuing in the blood after the primary disease has ceased, and causing the sequelæ which are so characteristic of diphtheria. It is also assumed that under special circumstances they may set up the disease in others by infection, and in the instance reported Dr. Hilliard infers that these "resting spores" were still potent for mischief in the case of the barely convalescent patient who came to Bierton, and that their influence was facilitated by means of gross sanitary defects at the house to which the patient came. Whatever be the correct explanation, it is certain that under some conditions the poison of diphtheria is capable of being communicated for some considerable time after the original ailment has subsided, and this has often been explained by regarding it as capable of attaching itself to plants and houses for a longer time than it does to individuals. In this case such an explanation would not account for the diffusion of the disease, but it is highly probable that the ichorous discharge from the nose and ear from which the convalescent was suffering was capable of communicating infection in the same way as the desquamating cuticle does in scarlet fever. Dr. Hilliard evidently inclines to this view.

SALT TAX AND CHOLERA.

ATTENTION has lately been drawn by questions in Parliament to the sufferings of the poorest classes in the Indian Empire, alleged to be due largely to the difficulty of obtaining common table salt. The difficulty arises, of course, from the high price of this article of diet, the result of the imposition of a Government tax. A society, the Indian Reform Association, has for some time been agitating to procure the abolition of this salt tax. A correspondent, who has this matter at heart, wishes us to give some information on the possible relationship that may exist between the want of salt and the occurrence of cholera in India. So far as we know, India was the birthplace, and unquestionably is the "home," of cholera. Whether the salt tax, by rendering a physiological necessary a high-priced luxury, is responsible for the origin and maintenance of cholera in India, is a question not perhaps of direct answer. No one would deny that, in a generally debilitated condition, disease is more prone to appear in persons suffering from chronic insufficiency of some essential article of food, and so a predisposition to cholera may be inferred to exist in those who are deprived of so important an element of food as salt. As the salts of soda are in greater excess in the fluids of the body, the diminution of salts in the blood in cases of cholera is easily accounted for by the great drain of fluids into the intestines. Precise scientific data do not exist to prove that excessive perspiration really needs to be compensated by the increased ingestion of salts; but on *a priori* grounds it would appear that such compensation should be made. It is highly probable that the deprivation of salt does tend to increase the liability of children to suffer from intestinal worms.

THE GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.

IN consideration of the great eminence of the late Dr. S. D. Gross as a surgeon, and his immense influence as a teacher in the medical schools of the United States, it has been widely felt that it would be a very fitting memorial of his career to establish a Professorship to bear his name in connexion with one of the American medical schools. The Alumni Association of Jefferson Medical College has inaugurated a movement to secure this, and has decided that the chair to be endowed shall be one for the teaching of Pathological Anatomy. Subscriptions towards the fund are to be sent to Dr. J. M. Barton, 1344, Spruce-street, Philadelphia. Dr. Gross had many friends and admirers in this country, and we are sure they will be glad of an opportunity of joining in such a worthy way of perpetuating the memory of a truly great man.

MEDICAL EVIDENCE v. "COMMON SENSE."

DURING the hearing of a charge of murder at the Manchester Assizes, a summary of which was given by our Manchester correspondent last week, Mr. Justice Day, in addressing the jury at the close of the evidence, expressed himself in very decided terms that the jury were compelled to stultify themselves by returning a verdict in accordance with the medical testimony, although their common sense must have told them that morally the accused was guilty. The deceased, Richard Saxon, sixty-five years of age, received on May 17th a severe blow from a hammer at the hands of his son Joseph, aged twenty-five. On presenting himself at the Ancoats Infirmary, the medical men were of opinion that the injury was not of a dangerous, much less of a fatal, nature. For the next two days deceased went to work, but at the end of that time he appears to have again lost a considerable quantity of blood from his scalp wound, and shortly afterwards to have passed into a state of coma, which ended in his death. It may be stated that the incidence of these grave symptoms was at the time of great mental excitement brought on by his dissatisfaction with the mildness of his son's sentence by the magistrate. At the post-mortem examination, made by Dr. Charnley Smith, a shallow depressed fracture of the skull was detected in the occipital bone. A partially decolorised blood-clot the size of a penny piece lay between the bone and dura mater, but there was no laceration of the brain, and no congestion or hæmorrhage in the superficial portion of the convolutions. In one lateral ventricle was a recent clot, which by its pressure had presumably been the proximate cause of death. The question the jury had to decide was, Had the original injury any causative relationship with the secondary ventricular hæmorrhage? Dr. Smith could not say that it had, and to this opinion we subscribe. It is true that, had the blow not been struck, the excitement of the deceased at what he deemed the insufficiency of the punishment inflicted on his assailant would not have arisen, and clearly Mr. Justice Day was not prepared to attach great importance to a point

Digitized by Google

so remote in its bearing on an issue of life or death. What evidence was there to justify the assumption that death might have arisen from natural causes? To our minds there was ample. Here was a man in all probability the subject of vascular disease; he was sixty-five years of age, addicted to intemperance, and crippled in one elbow from "rheumatic gout." The records of medicine show that it does not require any vast amount of physiological or physical strain to test unhealthy cerebral vessels beyond their power of endurance. From the absence of signs clearly connecting the initial injury with the apoplexy, and the presence of other conditions conducive to the attack both before and after the blow, we hold that the jury were morally as well as technically justified in acquitting the prisoner. We venture to differ from Mr. Justice Day as to the relative value in such a case of scientific testimony on the one hand and "common sense"—which by the way is often very uncommon nonsense—on the other. Dr. Bilton Pollard, of the Manchester Infirmary, was ready to support the position taken by Dr. Smith, but he was not called at the trial, as the judge ruled that Dr. Smith's evidence disposed of the case, a ruling with which we entirely agree.

THE WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

THE following gentlemen, being the active medical staff of this institution, have, we are informed, sent in their resignations: Drs. Heron, Dawson, Williams, Wolfenden, and Huggard. The late committee of management also declined nomination for re-election at the late annual meeting, consequent on the resolution which was carried impugning their decision in a matter that has occupied their attention for some months past. Mr. Proctor has also tendered his resignation of the office of treasurer, to which he was lately appointed. A protest has been lodged against the constitution of the late meeting, and a request made to the old committee and trustees not to give up their office until the governors have had an opportunity of expressing an opinion on the present state of affairs.

AID TO THE WOUNDED.

LAST week an important trial took place at Aldershot of an electric light waggon intended for lighting the field of battle at night to enable the wounded to be efficiently attended to. The demonstration, which was given at night, was intended to illustrate the application of the electric waggon in searching for, succouring, and transporting 100 men (representing the wounded) from the field to the dressing station, on the night after a supposed battle, by a bearer column of the Army Hospital Corps, with mule, mountain, and wheeled transport. Making allowance for the fact that there had not been time to test the machine effectually after its arrival at Aldershot, and to arrange an efficient code of signals, the trial may be deemed a success, the light being thrown over the field in such a manner as to materially assist in the search for the wounded and in applying temporary dressings. The principal drawbacks to it appear to be its weight (said to be three tons), and the difficulty which would no doubt be experienced with regard to transport. It cannot be doubted, however, that if these can be overcome the electric waggon would prove a very valuable adjunct to the surgical equipment of an army in the field. The trial was made under the personal superintendence of Baron Mundy, in the presence of a number of distinguished military and medical officers; among whom were the Director-General of the Army Medical Department, Sir Joseph Fayrer, Surgeon-General Mackinnon, Professor Longmore, and Dr. Farquharson, M.P.

THE LATE EDWARD VON JAEGER.

PROF. E. VON JAEGER, of Vienna, who died recently after a long illness, was born in 1818. His father, Frederich Jaeger, was Professor of Ocular Therapeutics at the Josephinum, so that from an early age his attention was directed to the subject that in after life he made his own. He graduated M.D. in 1844, and after some service in the army he abandoned the pursuit of medicine for a time in favour of mechanics. In 1850 he returned to the study of ophthalmology, to which the invention of the ophthalmoscope in 1851 by Helmholtz added considerable interest. In devising a less cumbrous instrument than the original ophthalmoscope, Jaeger made good use of his mechanical talent; and he set himself assiduously to study in this new field. Having examined numbers of healthy as well as of diseased eyes, he described and depicted the ophthalmoscopic appearances, thus laying the foundation of his well-known atlas. In 1856 he was named Extra-Professor, and in 1857 First Physician, to the Eye Department of the General Hospital; but it was only quite recently that he was appointed University Professor.

VACCINATION v. SMALL-POX.

LAST week we made certain remarks on the necessity and value of vaccination, as amply justifying its compulsory adoption as a preventive of small-pox. Dr. Cooper, medical officer of health for Widnes, relates a recent case which affords almost positive experimental proof to the same effect. A married woman, with an infant a few weeks old at the breast, was attacked with severe small-pox. The child was promptly vaccinated, and, though suckled throughout her illness and convalescence by the mother, did not take the disease. There can be hardly any doubt that in this case vaccination saved the child's life. Some, perhaps, may say that insusceptibility to the disease would equally account for the result. This could not be so, for in that case the vaccination, which was successful, must have failed, seeing that experiments by Ceely and Badcock, and by other later observers, have clearly shown that vaccinia and small-pox are one and the same disease. Genuine insusceptibility is a condition so rare, and so doubtfully existent, that it may practically be ignored. We have in Dr. Cooper's case a singularly concise illustration of the principle shown by M. Pasteur to apply to such maladies as anthrax and hydrophobia, and it is abundantly evident in the small-pox epidemics of this country, that the timely inoculation of a modified infectious disease will, other things being equal, infallibly prevent or mitigate the onset of a severer form.

WOOLSORTERS' DISEASE AT BRADFORD.

THE two inquests upon cases of woolsorters' disease at Bradford are still unfinished. The one is the case of Isaac Savile, in the employ of Messrs. Mitchell Brothers, who died on May 26th. The inquest was first adjourned to June 18th, and was continued on July 3rd and 21st, when it was again adjourned to August 20th, in order that the jury might have before them the new code of regulations upon the prophylaxis of the disease being drawn up by the Sanitary Committee. On the last occasion a conflict of medical opinion occurred—not, however, of much practical import. Thus Dr. Hime, the medical officer of health, who with Dr. Bell and others is assured that the deceased died of anthrax, was cross-examined at much length respecting the characteristics of the bacillus anthracis and the means taken to destroy it, and his evidence is in accord with the result of the researches of Koch and others. Dr. E. T. Tibbits, however, gave evidence to the effect that the bacillus anthracis was indistinguishable from putrefactive bacteria, and that woolsorters' disease had

Digitized by Google

no features distinct from those of blood-poisoning. The second inquiry is that on Catherine Cox, which was opened on June 30th, resumed on July 23rd, and adjourned to August 21st. Meanwhile an inquest upon a woolsorter at Saltaire was held by the same coroner (Mr. Barstow) on July 23rd. The man died in four days after the first onset of symptoms. He had been engaged in sorting Turkey mohair. Mr. Rutherford, surgeon, of Shipley, testified to the case having run the course of anthrax, and presenting morbid conditions (including the presence of bacilli in the blood) such as occur in this disease. The jury returned a verdict to the effect that the deceased died from woolsorters' disease, but that the firm (Sir T. Salt and Sons) had duly carried out all the regulations agreed to in July, 1880, by the masters and woolsorters, adding a recommendation to the firm to adopt any further precautionary measures that may be devised. Mr. Neil, on behalf of the firm, expressed their willingness to accede to that recommendation.

THE THIRD BLOOD-CORPUSCLE.

La Gazzetta degli Ospitali of July 16th publishes a memoir by Professor J. Bizzozero, "On the Pre-existence of Plastrine ("Blutplättchen") in the Normal Blood of the Mammalia." To obviate Weigert's objection, that observations on mesenteric vessels are liable to fallacy in consequence of exposure to the air, Bizzozero examined a living bat's-wing under the microscope, and he found that in all the bloodvessels, and at all times, the piastrine circulated, in addition to the red and white corpuscles. The piastrine of Bizzozero, the hæmatoblast of Hayem, is the visible form of a series to which Dr. Norris has given the general title of the fugitive discs of the blood. In a letter dated Jan. 23rd, 1882, which was published in this journal, Dr. Norris succinctly stated his claim to priority in the discovery of the existence and function of the new blood-corpuscle—a matter capable of physical demonstration, and yet in controversy between the leading histologists. Is the third blood-corpuscle a reality or an optical delusion? If the former, who discovered it, and what are its properties?

CANCER OF THE BREAST AND PREGNANCY.

As an illustration of an untoward conjunction of events leading to corresponding difficulty in treatment, M. Larger brought before the Société de Chirurgie an account of the following case:—The patient is a young married woman in the fifth month of pregnancy, and suffering from an ulcerating tumour of the breast, regarded as of an "encephaloid" nature. The general health is said to be excellent. The tumour, though malignant, appears to be strictly limited to the glandular tissue, and bled at times profusely. MM. Trélat, Polaillon, Terrillon, Guéniot, and Verneuil all advised immediate operation.

HOSPITAL SUNDAY FUND.

It affords us great gratification to be able to announce that the amount already received on behalf of the above fund is between £100 and £200 in excess of last year's total of £33,935, and the receipt of another £500 may fairly be expected before the close of the financial year on Oct. 31st. The amount to be received from the managers of the very successful hospital *fête* held at the Health Exhibition on the evening of the 23rd ult. will be handed over by the Lord Mayor to the Council of the Hospital Sunday Fund for distribution, though separately from the proceeds of the fund.

NEARLY one hundred persons have been made ill at Brooklyn by eating ice cream in which acetate of copper was present.

IN consequence of recent legal proceedings, Sir Henry Holland has placed before the Government a suggestion that reports as to the working of the lunacy laws on the Continent shall be ordered for for presentation to Parliament, special attention being paid to the following points:—Whether there are private as well as public asylums; what are the checks against improper admission or detention of persons in an asylum; what supervision and inspection, if any, are exercised by any public and recognised authority; and the nature and powers of such authority.

A REDUCTION of 50 per cent. on the published tariff is allowed to members of the profession attending the forthcoming International Congress of Hygiene and Demography, on production of their "carte d'inscription," by (*a*) the Company for the Exploitation of the State Railways in the Netherlands, (*b*) the State Railways of Belgium, and (*c*) the Réseau du Nord Français.

AT a well-attended public meeting of residents in the neighbourhood of the Hampstead Small-pox Hospital a resolution calling upon the vestry of Hampstead to take prompt and energetic action to secure the abolition of the hospital was carried unanimously. A resolution in favour of the establishment of local hospitals for each parish or district was also carried.

MR. BAILEY DENTON, who is perhaps more widely known as a sanitary than as an agricultural engineer, has received from the French Government the distinction of the Cross for "Mérite Agricole." We believe that it is to Mr. Bailey Denton that tenants-for-life chiefly owe their power to charge their estates for agricultural improvements.

IT is stated that Sir Charles Dilke has made arrangements for an inspection by the medical staff of the Local Government Board of the sanitary arrangements at the principal ports of the United Kingdom. The inspection will, it is understood, be made immediately.

WE learn that on the 25th ult. Dr. Elder performed nephrectomy, for the third time, at the Hospital for Women, Nottingham, and that the patient so far is progressing satisfactorily.

AN eburnated exostosis of the frontal bone, filling up the orbital cavity, has been removed by M. Badal by means of mallet and chisel, healing taking place without damage to the eye or vision.

DR. BATORSKY, a surgeon attached to the department for foreign affairs, has left St. Petersburg for Bagdad, in order to join a medical board deputed to investigate the outbreak of plague in that district.

THE eighth International Medical Congress will commence its sittings at Copenhagen on Saturday the 16th inst., and the session will continue till the 16th. A full programme of the proceedings will be found in our impression of June 7th.

AT a special meeting of the Macclesfield Board of Health held on the 24th ult., a scheme proposing the expenditure of £5000 on an infectious disease hospital was rejected.

PRESENTATION.—Mr. H. W. Langdon, M.R.C.S., on his retirement from the medical charge of the members of the Foresters' Court, Devizes, has been presented with a testimonial in the shape of a handsome pair of emblems, framed in oak, and inlaid with gilt.

Pharmacology and Therapeutics.

HYDRASTIS CANADENSIS.

M. SCHATZ has employed a fluid extract of this drug in fifty cases of uterine hæmorrhage due to various causes. The results have been very satisfactory in about two-thirds of the cases. Metrorrhagia due to fibroid tumours, post-puerperal menorrhagia, and menorrhagia about the time of puberty, were the affections most readily relieved. The fluid extract has been given in doses of twenty drops three times a day. The treatment was begun a week or more before the commencement of the period of menstruation. Under its influence the duration of the catamenia was diminished and the blood discharged was lessened, and in some cases there was actual suppression. M. Fellner has investigated the physiological action of the fluid extract of hydrastis canadensis on dogs, and attention was strictly confined to the vessels, heart, small intestine, and uterus. In large doses (two to five grains) the fluid extract injected directly into the veins momentarily raises the intra-vascular pressure; but this first phase is soon followed by another in which the blood-pressure sinks permanently below the normal level, and death may ensue. When doses of 1·2 to 1 gramme are employed in the form of hypodermic injections, the lowering of the blood-pressure is less pronounced and takes longer to appear, but it is still persistent. At the same time the elevation of the intra-vascular pressure lasts a longer time. In still feebler doses the initial effect is, on the contrary, a diminution of the blood-pressure of very short duration; and the secondary effect is an elevation of the blood-pressure, which persists indefinitely. When a number of minute doses are injected in succession, the final result is the same as with a single dose. The subcutaneous injection of a strong dose (two grammes) determines, first, a transient decrease in the blood-pressure; this then passes away for a brief period, to be again followed by a fresh lowering, not in a continuous fashion, but by a series of well-marked oscillations. The results are the same when the drug is given by the rectum or stomach. Previous section of the splanchnic nerves does not appreciably modify the effects produced by intravenous injection of small or large doses of the fluid extract. The same fact holds good of compression of the abdominal aorta. Section of the cervical portion of the spinal cord does not stop the action of the drug in lowering blood-pressure. Strychnia can to a certain extent undo the effects of hydrastis on the blood-pressure. By direct inspection the small intestines are observed to be injected during the period of lowered blood-pressure, and to be exsanguineous when the blood-pressure is raised again. Hydrastis is believed thus to have a powerful effect on the vaso-motor apparatus, due to an excitation of the cerebral centres. During the first stage of the action of the drug the pulse is slowed. This delay may go on to complete arrest of the heart's action; it appears to be due to excitation of the central end of the vagus, because it does not occur when the pneumogastric nerves are divided. After the injection of large doses the slowing of the pulse with syncope is met with during the second stage, when the blood-pressure is diminished. In this stage previous division of the vagi exercises no influence on the frequency of the heart's action. All injections give rise to contraction of the womb, both of its body and horns; the maximum effect is produced a short time after the injection—later on, however, manifest contractions do take place, chiefly of the cornua. The uterine contractions synchronise with the contractions of the blood-vessels.

SIZYGIUM.

The fruit of Sizygium jambolanum, an East Indian plant belonging to the natural order Myrtaceæ, has recently been somewhat in demand on the Continent for use in the treatment of diabetes. M. Banatrala has found in three cases in which he has tried it that its use led to a diminution in the amount of urine secreted, and that it caused the disappearance of the sugar. These results were manifested in forty-eight hours after taking the medicine. During the time that the patients were submitted to the action of the drug they could take amylaceous food with impunity. The astringent rind of the fruit seems to be the active part.

HAZIGNE.

Professor Baillon has described a Malagasy plant called "hazigne" in the *Journal de Pharmacie*, the fruit of which yields an oil and the stem a resin, which are used by the natives as a remedy in certain skin diseases, such as leprosy, the itch, and ulcers. The oil obtained from the seeds is also used as food and for lamps. The hazigne is a handsome tree belonging to the Guttiferæ, and is named Symphonia fasciculata. The fruit is known to the natives by the name of "voa-sou-vouara."

PHASEOLUS LIMATUS.

The pois d'Achery is a sort of kidney bean which is cultivated in the Mauritius and used there as an occasional article of diet by the Creoles. It exists in two varieties: the one white, which is generally wholesome; the other prettily variegated, which is regarded as poisonous. The poisonous character is due, according to Davidson and Stevenson, to hydrocyanic acid, which is formed when the beans are macerated in water by a process similar to that by which it is produced in certain plants of the Rosaceæ, such as the almond and cherry laurel.

PALILLO.

A Mexican plant, which appears to be Croton morifolius, has recently been the subject of experiment by Messrs. Duges and Armendaris. Two or three drops of the oil contained in the seeds act like a moderate dose of castor oil. The natives of Mexico use the leaves of the plant in the form of infusion as a remedy against gastralgia and atony of stomach. The tincture of the leaves is said to give excellent results in neuralgia, especially of the face, either when used as a liniment or dropped into the ears, or taken in the dose of ten or fifteen drops in orange-flower water (*Pharmaceutical Journal*).

TUTU.

The "tutu" plant (pronounced "toot") is indigenous to New Zealand; its botanical name is Coriariæ ruscifoliæ. Tutu is a poison under certain conditions and for certain animals. The horse and pig are said to resist its poisonous action. Springtime appears to be the period of its greatest activity; when the succulent shoots thrown up from the spreading roots are ingested on a full stomach the effects are greatly modified. Mr. Hustwick, from whose account in the *Pharmaceutical Journal* we have abstracted this information, says that the system may become accustomed to the poison taken gradually. The chief effects of the plant is on the nervous system; the animal eating it appears to have the "staggers," becomes lethargic, but is liable to fits of frenzy, the occurrence of which may be due to slight provocation. These violent attacks of madness seem to recur at rapidly decreasing intervals, until the animal at last succumbs from sheer exhaustion. Phlebotomy performed on the jugular vein has been vaunted as a cure for these symptoms, but apparently on insufficient grounds. The effect of the green herb on man is not known, but the "berries" when ripe are said to be grateful and refreshing to the thirsty, though care must be taken to reject the seeds. Small birds enjoy the ripe fruit without inconvenience. Goats may eat the plant with impunity. Ruminants are, for the most part, however, seriously affected by it.

KAIRIN.

The physiological effects of kairin have received further study at the hands of M. Morohewetz, agrégé in physiology at the Faculty of Moscow. It appears from these investigations that the alkaloid kairin does not spend its activity in lowering the temperature. Kairin was used in a 6 per cent. (*sic*) solution of chloride of sodium, in order to prevent the action of the distilled water on the red blood discs. The blood remained alkaline, but its colour changed, and the more rapidly the greater the degree of concentration of the solution employed. A continuous current of air deprived of its carbonic acid did not restore the red colour of arterial blood. The blood spectrum indicated the presence of met-hæmoglobin by the appearance of four bands between the C and F of Frauenhofer's lines; these bands were more evident in proportion to the strength of the kairin in the solution. The red blood globules become dome-shaped under the influence of kairin; their colour is changed to that of a brownish tint and is paler according to the degree of concentration of the alkaloid. The number of red discs is not diminished. The blood of dogs which have ingested kairin coagulates almost instantaneously after escaping from the bloodvessels. The

Digitized by Google

change in the colour of the blood is seen in the living animal as a cyanosis of leaden tint, and this is said to have been witnessed in man by M. Golouboff as the result of the administration of 70 centigramme of kairin. The salivary and bilious secretions are made more abundant by the injection of the alkaloid under the skin or into the duodenum, the bile becoming black and viscous. A reddish-yellow ring, situate between fuming nitric acid and urine, is the test for the presence of kairin in the renal secretions. An elevation, followed by a depression, of the blood pressure in the carotid arteries and intense dyspnœa have been observed to follow the administration of large doses of kairin. In the dog 1·80 grammes of kairin is said to paralyse the heart first, respiration proceeding and taking on the character of Cheyne-Stokes breathing. At the autopsy the cavities of the heart are found to be dilated and full of blood. In the frog, kairin is said, like curare, to paralyse the terminations of the peripheral nerves. Newiadomsky has observed great prostration and cyanosis in a case of pneumonia after the administration of ·40 centigramme of kairin.

OSMIC ACID IN EPILEPSY.

The employment of osmic acid in epilepsy suggested itself to M. Wildermuth from the value of the drug in cases of neuralgia. At first the acid was used, but later an osmiate of potassium. The medicament was administered as pilules, each containing one milligramme of the active substance. The maximum daily dose employed was fifteen pilules, or fifteen milligrammes. Thirteen patients, the subjects of confirmed epilepsy, were under observation. The remedy was first combined with bromide of potassium, but this method was not followed by good results. Under the sole influence of the osmiate the number of attacks was steadily diminished, as compared with their frequency on expectant treatment. In only one instance, however, was complete immunity conferred.

AMYL NITRITE.

In the second number of the *Asclepiad* Dr. Richardson gives a formula for the administration of amyl nitrite by the mouth:—Amyl nitrite, pure, ℿxxxvi.; ethylic alcohol (sp. gr. 830), ʒvi; pure glycerine to ʒiss. To make a mixture of twelve doses. One fluid drachm to be taken in a wineglassful of warm water. In asthma this method is specially recommended.

THE INTERNATIONAL HEALTH EXHIBITION.

THE FRENCH SECTION.

[SECOND NOTICE.]

HAVING dealt with water-supply and drainage in our previous article on the French section, warming and ventilation, with the construction of hospitals, barracks, schools, &c., suggest themselves as bearing most directly on the preservation of health. In these departments the French have made more progress than in the matter of drainage. Indeed, so far as hospital construction is concerned, it is generally admitted that the Tollet pavilion is the best in Europe. Such was the opinion expressed by Dr. F. J. Mouat in his remarkable reports on hospital construction throughout Europe, published in these columns. For simplicity, cheapness, and thorough ventilation, the Gothic arch, which is the chief feature of the system, gives the best results. It would take too much space, however, to recapitulate all that has been said on this subject; but the attendants at the Exhibition have for distribution a capital little pamphlet containing the catalogue and explanations of the Tollet exhibits published in English, which gives very full information. Behind the dairies will be found a perfect embodiment of the model which has just been definitely and officially adopted by the French Ministry of War for the army. This tent is upheld by the iron framework which is permanent as in temporary structures, forms the sole support of the Tollet pavilions. No pickets are necessary, and in being exposed to the most violent winds on the coast of Tunis these tents withstood the pressure when all the ordinary tents were blown down. There are some sixty models and drawings at the Exhibition of the Tollet system in all its applications.

Equally prominent in the French section are the drawings, models, &c., of Messrs. Geneste and Herscher's systems of heating, ventilating, &c. They have also issued, in English and French, a bulky volume explaining their exhibits. To them is due the ventilation of the Hôtel de Ville and the principal primary schools of Paris, the law courts, and the Monnaie Theatre of Brussels, the Grand Theatre of Geneva, the Ferrari Asylum at Clamart, the prison at Nanterre, and a great number of other important buildings. This firm has brought out a mechanical ventilator which is used at the Anzin coal mines and at the Hôtal de Ville. Formerly large ventilators only yielded 50 to 70 per cent. as as compared to the motive power employed. Messrs. Geneste and Herscher's ventilator gives 83 per cent., whilst its moderate dimensions permit of its being introduced in small passages and other inconvenient places, which is of the utmost importance in preserving the health of mining communities. With a dynamomotor a small mechanical ventilator is introduced at different points of public buildings and pumps forward the required air supply. Models of schools show how they are warmed in such a manner as to ensure ventilation and secure the utmost economy. The theory and practice here involved are complicated, but the result compares very favourably with what has been done in England; draughts are avoided, the cooling influence of the window counteracted, and the warmth is equally diffused throughout the room. There are also some interesting drawings showing how the workmen engaged at Messrs. Christofphe's silver-plating works are protected from the nitrous fumes. A lip overhangs the rim of the cauldron, and the suction produced underneath draws away the dangerous vapours. For steel works also there is a system of drawing off the small particles that otherwise would prove so dangerous to the workmen. In all these matters Messrs. Geneste and Herscher have displayed great enterprise and much scientific and engineering knowledge.

With respect to education, we are glad to note how the natural sciences are taught in the primary and secondary schools, both girls and boys being made to draw and describe all the principal organs of the human body, also various animals and subjects illustrative of elementary physics. By the adoption, now very general throughout France, of unilateral light, initiated and so ably advocated by M. Emile Trélat, the French are certainly in advance of England on this important question. While in English schools rays of light of different intensity coming from different directions cross each other, and confuse and fatigue the sight of the students, the light in a French school comes in one steady stream from large windows on the left hand side of the class. Excellent drawings illustrate this principle, and show it is only after class hours that the windows on the other side of the room may be opened, and this solely for the purposes of purification. The numerous plans of schools indicate a preference for pavilions or detached buildings, and the ample provision for drilling and gymnastics is highly commendable. The school furniture, though good, does not offer any special advantage over what is shown in other parts of the Exhibition, and we should like to see better provision made for the varying stature and growth of the pupils.

Among the miscellaneous exhibits within the Court, the appliances for blowing glass with compressed air will be welcome to all who know the injury done to the workmen engaged in glass-blowing. Not only is the strain upon the lungs most exhausting, but, by passing the blowing tube from one man to another, diseases, especially syphilis, are often communicated. Now, however, Messrs. Appert Brothers have put an end to these risks; and not only do they preserve the health of their workmen, but, as with compressed air they can bring much greater power to bear, they are able to exhibit a huge globe out of which 5000 watch-glasses can be cut. Just opposite this exhibit will be found Papier's ventilating cowls, which by imparting a rotary motion to the air that enters them are supposed to acquire over an ordinary chimney or pipe some of the superiority of the rifle over a smooth-bore. The theory is interesting, but we do not exactly understand what it has to do with the French Court, as the firm is established in England, and the list given of the places where the ventilator is applied are all in England.

Leaving the centre of the Court and going outside of the surrounding wall, exhibits of a less serious but of a more popular description will be found. For instance, there are the celebrated French soups of the Société Générale des Potages Economiques de Paris. These we analysed on a former occasion,

Digitized by Google

and found most nutritive, in spite of their wonderful cheapness. They present a great variety of flavours, need only to be boiled for a few minutes to be ready for consumption, and at an outlay of less than twopence per head. We get the clearness of the French soup and the peculiar familiar flavour so often missed in English soups. Close at hand the exhibits of M. Martin Brey of Paris are of some interest, as showing that macaroni, vermicelli, &c., can be made in the north. Formerly Lyons and Italy had the monopoly of this trade; for a powerful sun was required to dry the paste, so that it can be preserved indefinitely, as the smallest proportion of water may determine decomposition. M. Brey now, however, employs a stove specially contrived for drying paste, and he is therefore quite independent of the sunshine. It is said that 1,000,000 kilos of Italian macaroni and other pastes are manufactured annually in Paris. Among the familiar French beverages exhibited we recognised the Grande Champagne liquor of Barabeaux père et fils, and Get's peppermint. The latter is a mixture of syrup, alcohol, and peppermint, and forms, when diluted with water, a wholesome refreshing summer drink. Gellé Frères give us some French perfumery which has a special elegance that can only be described as truly Parisian. In their bearing upon health, the soaps, &c., have their hygienic virtues on the liberal admixture of glycerine; but, apart from this advantage, French perfumery has always been an attractive luxury. The café hygienic of Messrs. Marshall and Co., of Lyons and Paris, is peculiar. It tastes like ordinary coffee, it is the price of ordinary coffee, but is made of mocha and torrified acorns of the South European species. It therefore professes to be a food and a stimulant that will not cause sleeplessness. The preparations of chestnut flour of the same firm are very useful as helping to bring into general use a plentiful and excellent article of diet. The well-known chocolate Lombart also possesses similar merits. A large painting on the wall shows the vast underground passages that pass beneath this celebrated chocolate manufactory. The air is drawn down into these passages from a chimney that rises above the impurities on the surface of the ground, it is moistened, cooled underground, and then delivered into large cases in the factory above at exactly the same temperature in every season. These cases, thus cooled, receive the warm chocolate in moulds, and harden it in its right shape. Nearly as pleasant as these bonbons, Dr. Laféron's liqueur will be found a most enticing preparation of iron and quinine. It is an after-dinner liqueur, in which bitter oranges, myrrh, colombo, quinine, and iron are associated without injuring the palatable effect of the beverage. Dr. Laféron is a well-known practising physician in Paris.

In conclusion, the French may be warmly commended for the success of their section, though it was prepared under great difficulties. The invitation, lost in the pigeon-holes of the French Ministry, was only made known after the time for application for space was already terminated. On the other hand, the Government could only contribute £120 towards the expenses. In spite of these discouraging circumstances, and by private initiative, each exhibitor subscribing to the expenses, the money was found, and a very complete exhibition organised. The chief French commissioner, Dr. A. J. Martin, with great skill and energy secured the support of those friends of sanitary reform whom he knew most capable of entering into the spirit of such an exhibition. The love of science and of country aiding, the desired end was attained. The section was opened a month late, but, under the circumstances, this could not be avoided. The decorations and installations were all arranged with much taste by Messrs. Joubert and Sons, who also fitted up a small renaissance saloon for the French commissioners, and, by their knowledge of English and French, contributed materially to success in carrying out the scheme which at the eleventh hour had been so hastily yet well prepared.

ESSEX AND HERTS BENEVOLENT MEDICAL SOCIETY.

The ninety-eighth annual general court of audit of this Society was held at Hertford on the 15th ult., when petitions for relief were received from eleven widows and two medical men, and grants amounting to £433 were made. The Society has up to the present time received in subscriptions over £25,000, and has granted for relief over £30,000; the funded stock now amounts to £9800, and it is hoped that £10,000 may be invested before the centenary of the Society.

THE CHOLERA.

THE hope we ventured to express last week as to the diminution of the cholera epidemic at Marseilles and Toulon has so far been realised that, with the advent of the mistral and the diminution of temperature, the daily number of fresh attacks has been reduced to about half that which obtained about a fortnight ago. But, notwithstanding this, the disease is steadily extending its area; some twelve or more towns and villages in Provence and the south have become attacked; and in a few places, as at Arles and Aix, the onset of the disease has been of considerable virulence. The infection has also travelled into Italy, but so little confidence is reposed in the public by those who are there in authority that it is extremely difficult to judge whether the disease is being kept within the bounds of the localities first infected, or whether it is diffusing itself. Whatever be the future course of the disease, this is certainly not the time in which to relax any of the sanitary measures which have for their object the removal of all filth conditions which favour the retention and diffusion of the cholera poison. Even Marseilles and Toulon will be by no means out of danger, even if the number of fresh attacks goes on progressively diminishing, for where cholera has found the material favourable to its vitality it has not failed to show itself even in the depth of a Russian winter, and places that are attacked this year will certainly be liable to a renewal of the epidemic next autumn if they do not efficiently rid themselves of all sources, by which excremental contamination of air and water may be brought about. In the midst of such conditions the poison will hardly fail to lie dormant; if they are removed, the poison will doubtless be at the same time got rid of. So far all rumours as to the actual importation of cholera into this country have turned out to be without foundation, although the sanitary defences at two or three of our ports have been put to the test. On rigid inspection and immediate isolation primarily in our port sanitary districts, and on measures of sanitation and isolation in all the sanitary areas of the country, the advisers of our Government have decided to rely; and we are glad to observe that with the aid of their own staff, and by the help of additional skilled physicians who have acquaintance with cholera and with the measures of prevention with which the disease must be met, the Local Government Board have commenced a special inspection of the sanitary arrangements which are in force at our principal ports. The influence of visits thus paid by officers from the central authority can only be useful, and in many districts they will be helpful in the extreme in enabling authorities who are hesitating as to the measures they should adopt to arrive at a right decision. In the meantime, all needed sanitary work should be pressed forward, and an attitude of watchfulness maintained.

Dr. Marckowitz, the Bucharest physician who has gone to study the cholera in the south of France, takes a more hopeful view of the situation than his Berlin *confrère*, Dr. Koch, who predicted that the epidemic would extend its ravages all over Europe, and is inclined to believe that it will die out where it originated. M. Claretie, in a recent *chronique* in the *Temps*, mentions a rather sensational case of recovery from cholera during one of the earlier visits of the epidemic, due to the skill of Dr. Lorain, a well-known physician of the time. The patient had sunk into the last stage of collapse, and the hospital physicians had stopped the treatment as useless. Dr. Lorain, happening to enter the ward, determined after a hasty examination of the sufferer to try an experiment with the object of restoring the circulation, which had practically ceased. He first performed the operation he contemplated on a rabbit, into whose crural vein he injected a certain quantity of warm water. He then repeated it on the dying man, into whose circulatory system he pumped 400 grammes—nearly a pint—of the same fluid. The heart began to beat at once, though so faintly as to be hardly perceptible. The operation was repeated with still happier effects. The pulse could now be felt at the wrist; the patient recovered sensibility and voice. In ten days he left the hospital perfectly well. As M. Claretie remarks, the case, which is a well-authenticated one, illustrates the soundness of Dr. Koch's advice, never to despair

Digitized by Google

of a cholera patient, and to keep up the treatment to the very last. The health of Paris continues to be satisfactory. Lloyd's agent at Lisbon states that the Portuguese Official Gazette of the 26th ult. contained a sanitary bulletin declaring the port of Huelva infected with cholera, and considered as suspected the ports between Cadiz and Ayamonte, both inclusive. The Paris delegates have visited Marseilles and Toulon. M. Clemenceau, who is a medical man as well as a deputy, speaking on sanitary measures at a meeting of the municipal council of the former city, proposed a central committee of medical men, and expressed himself in favour of the hospital being transferred to the outside of the town. There are now in Paris some 14,000 fewer visitors than were present at this time last year. It is stated that twenty cases of cholera have occurred at St. Petersburg, and that the disease has appeared at Charkoff and other towns. They have, however, been on the whole of a mild character, and the patients have recovered.

THE SUSPECTED CASE OF CHOLERA AT LIVERPOOL.

On the 25th ult., one of the crew of the *St. Dunstan* steamer was seized with severe cramp in the limbs and stomach followed by vomiting. This happened while he was transacting business in the city. He was taken home in a conveyance, and Dr. Welsh of the South Dispensary visited him at once. As the case appeared to be of a serious character, and as the patient had come from a vessel on board which two men had recently died with all the symptoms of cholera, Dr. Welsh very properly sought further advice and assistance. Dr. Lindsay and Mr. Hutchinson attended, and under their treatment the patient soon recovered. Dr. Taylor, the medical officer of health, also visited the patient. It is very satisfactory to note that the thorough disinfection of the vessel with the other precautions adopted, as mentioned in last week's LANCET, has proved successful, no other case having occurred. It ought to be mentioned that the sanitary authorities were enabled to do more in this case than the Health Act authorised, the owners having placed the vessel entirely at their disposal.

THE PICTORIAL PRESS AND CHOLERA.

The *Graphic* published last week some humorous sketches of the manner in which our continental neighbours put into practice the sanitary cordon and the fumigation of passengers. The dipping of a dog, which had, by mistake of course, violated the regulations by crossing the cordon, into a bucket of vinegar by way of disinfection is as amusing and grotesque as the bargaining by bribery for getting poultry across the cordon, with policemen watching complacently over this little transaction, and the fumigation of the persons of passengers—the former being carried out by the Spanish authorities at Gibraltar and the latter by the French at Avignon. In another page we notice a "cholera fumigating box," by which it would seem that still more stringent precautions are adopted at Geneva. "The suspected person," says the *Graphic*, "is placed in a box, which is about 6 ft. high, and in which he stands upright, with only his head outside, a towel being wrapped round the neck. The process occupies from three to four minutes, and the disinfectants used are chloride of lime and carbolic acid. The top piece of the box is made to slide in, and is removed when the process is completed by simply pulling outwards. While the sliding-board is being removed the towel comes in handily as a respirator."

NEW CHOLERA PRECAUTIONS AT LEITH.

In support of our remarks last week, we now learn that the sanitary authorities at Leith have received a communication from the Board of Trade informing them that a vessel had sailed from Marseilles with a cargo of old rags, and instructing them to be on the alert in case it should go to Leith. We trust that effective measures will forthwith be adopted in view of preventing at this juncture the importation of old rags and such-like media for conveying the cholera virus, especially when they happen to come from infected places.

Charles George Guy Perceval, Esq., H.B.M.'s Consul at Marseilles, has, we are informed, consented to receive contributions &c. towards relieving the distress among the labouring poor of the town induced by the epidemic now prevailing there.

The master of the steamship *Bracadale*, bound from Calcutta to Demerara, with nearly seven hundred souls on board, on the arrival of the vessel in Table Bay on the 4th ult., reported that cholera had broken out during the voyage, and that eighteen fatal cases had occurred.

The National Health Society has prepared for circulation a leaflet containing a variety of plain instructions for the prevention of cholera, and mentioning the precautions which it is desirable to take in the event of the appearance of an actual case of the disease.

THE FORTHCOMING OTOLOGICAL CONGRES AT BALE.

THE programme of this Congress, the third of its kind, which is to be held at Bâle from September 1st to 4th, has been published. The opening meeting will commence on September 1st at 10 A.M., when the election of officers will be held and addresses delivered by Dr. Sapolini, the President of the last Otological Congress, by Professor Burckhardtmerian, the President of the Organisation Committee, and by the members delegated from the Haut Conseil Fédéral and the Conseil d'Etat du Canton de Bâle-Ville. At 12.30 P.M. a breakfast will be given by the Swiss aural surgeons at the Veltlinerhette, and from 3 to 6 P.M. a meeting of the Congress will be held. On September 2nd, 3rd, and 4th meetings will be held from 9 A.M. to 12, and from 3 to 6 P.M., and on the 3rd the members will in the evening be entertained at a dinner given by the Conseil d'Etat of the Canton de Bâle-Ville. For September 5th an excursion to the lake of the four cantons is projected. The official languages are French, German, English, and Italian. The subscription is fixed at 20 francs, and tickets of membership may be obtained on application to Dr. Courvoisin, Bâle. In the list of communications promised, which number thirty-eight, we notice the names of but two residents in the United Kingdom—Mr. Bendelack Hewetson, who will read a paper on the Immediate Relief from Earache by the Injection against the Membrana Tympani of Glycerinum Acidi Carbolici, and its Power in arresting the Progress of Inflammation in the Middle Ear, of which the Earache is a symptom, and deliver some remarks on the Treatment of Catarrhal Deafness by the daily Injection of a strong Solution of Sodæ Bicarbonas into the Nares by the patients; and Dr. Thomas Barr, who has promised a paper on Adenoid Vegetations of the Naso-pharyngeal Cavity.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Barton, Winton, Eccles, and Monton (*Urban*). — The urban sanitary district bearing this composite name, which is approximate to Manchester and Salford, had in 1881 an enumerated population of 21,786. The medical officer of health, Dr. Carrington, has recently issued an interesting report for the two years 1882 and 1883, in which he has good reason for congratulating the sanitary authority and himself upon the evidence of improving sanitary condition that the recent mortality statistics for the district afford. The death-rate in the district which averaged 23·0 per 1000 in the four years 1873-76, fell to 18·3 in the four years 1880-83. In 1883 the death-rate was only 16·2, and Dr. Carrington estimates that 161 persons were alive in his district at the end of the year, whose deaths would have been recorded had the death-rate that prevailed ten years ago been maintained. We should have liked to see mentioned in the report the method adopted for estimating the population of the district, for whereas it appears to be admitted that the population declined from 1878 to 1881, it is now assumed to be increasing again, notwithstanding the decrease in the number of recorded births. The statistics given suggest the probability that the present population is somewhat over-estimated. Although so much undoubted improvement in the sanitary condition of the district has evidently taken place in recent years, the zymotic death-rate, reduced though it is, shows that the mortality is susceptible of further reduction; indeed

Digitized by Google

Dr. Carrington admits that "there are plenty of insanitary cottages in our midst." The proportion of child mortality is still exceedingly high, although the report does not give the means for measuring it satisfactorily, by showing the proportion of deaths of children under five years to those living at those ages. This is a test of sanitary condition which should always find a place in health reports. The inspector's report shows that a vast amount of useful work has recently been done, and no one need hesitate to refer to this work, and the reduction of the death-rate, as cause and effect. The result should encourage further effort in the same direction.

Stratford-on-Avon Combination.—Mr. Fosbroke, who has now held office in the Stratford-on-Avon combined district for over ten years, reports an annual mortality at the rate of 15·2 per 1000 inhabitants, and a birth-rate of 32·1. The sanatorium at Alcester has, as during former years, been of considerable service, and at Bidport an outbreak of German measles was stamped out by its aid. Scarlet fever appeared in ten different localities, but nowhere did it assume extended proportions. Thirteen cases came to Mr. Fosbroke's knowledge where speedy removal to the sanatorium prevented any extension of the disease, even to other members of the infected houses; a result which must, doubtless, be attributed in part to the system of voluntary notification of infectious diseases which has been organised in this district. Diphtheria was prevalent, although but little fatal, in this district, and Mr. Fosbroke inclines strongly to the opinion that ordinary sore-throat may by progressive development eventually produce the characteristic disease. Together with the medical officer to the Alcester Workhouse, Mr. Fosbroke investigated an outbreak of seventeen cases of diarrhœa in that establishment, and, after taking voluminous evidence, they came to the conclusion that the illness had been brought about by the consumption of soup cooked in a dirty copper furnace. The fact that the outbreak subsided immediately this culinary vessel was cleaned confirms the view expressed. The excellent sanitary work which has been organised in this combined district continues steadily in progress. The Evesham urban and rural districts are about jointly to erect a hospital for infectious diseases, new bye-laws have been framed by the Stratford and Evesham urban authorities, and the Alcester Board have delegated a similar work to a committee of their own members.

Jarrow (Urban).—The population of this district is calculated at some 28,000, and the death-rate was as high as 23·4 per 1000, whereas for the triennial period 1881–83 the mean was 21·4. Even this, however, exceeds last year's average death-rate of 20·4 in the fifty large towns of England. To some extent the excess is regarded by Dr. Munro as due to considerable fluctuations in population following on variations in the shipbuilding industry, and he is able to point to some diminution in the infantile death-rate. On the other hand, the zymotic death-rate reached 5·1 per 1000. Measles caused 82 deaths, small-pox 6, fever 8, and diarrhœa 28. The former disease is not one which requires notification under the Jarrow Improvement Act. This is unfortunate, because, although it is not often that much can be done to stay its spread by isolation, disinfection, and improved sanitary measures, yet much can be done in that direction in connexion with the closing of schools and the exclusion of scholars from infected houses. Out of 434 cases of infectious disease which were notified, and which happened to include many cases of measles, the only cases admitted into the infectious hospital were 25 small-pox and 1 typhus; thus affording another instance of the comparative failure of these temporary buildings. Not one out of 143 scarlet fever cases which came under notice was thus isolated. Short of isolation, considerable efforts are made by Dr. Munro's staff to control the spread of infectious diseases, and special pains are taken to see that the sanitary state of the schools, which form such fertile centres of infection, is maintained at a proper standard.

Lytham (Urban).—Excluding deaths occurring amongst casual visitors, the death-rate for 1883 reached only 12 per 1000, and two deaths were registered from zymotic causes. The general death-rate has also undergone a steady annual diminution, and Dr. Fisher maintains, with justice, that Lytham has a claim to be regarded as a salubrious health resort. The list of actual sanitary works carried out shows that a genuine effort is made to ensure the result attained.

Scarborough (Urban).—In the borough of Scarborough the death-rate in a population of 32,150 was 18·8 per 1000, and the zymotic rate 1·3. Scarlet fever was somewhat prevalent during 1883, six deaths from this cause having taken place during both the second and the third quarters. Scarborough is especially liable to receive infection from without, and the corporation have hence provided themselves with an infectious hospital, a fever ambulance, and one of the best-known disinfecting stoves. We fear, however, that the hospital is but rarely used, and it certainly is not such a one as should be possessed by a health resort like Scarborough, where visitors needing isolation demand a superior class of accommodation. Care is evidently bestowed by Dr. Taylor on all the sanitary details of the town, and the best efforts are made by him to maintain the healthiness of the borough.

Bedford (Rural).—This is an extensive district, having a scattered population of some 23,000. The death-rate, 19 per 1000, must be regarded as high. Diphtheria has for some years past maintained a steady hold on this and some neighbouring districts, and Dr. Prior, who has given very careful attention to its mode of origin and distribution, is inclined to fear that it is getting established in the locality. During 1883 the deaths were scattered over various parts of the district, no severe outbreak in any one place having occurred. In this report Dr. Prior calls attention to the sad lack of space about houses in some of the villages, and to the resulting courts and yards which resemble those of our large towns. It is often held that bye-laws needed in towns are not applicable to villages, but their adoption is the only way to prevent occurrences such as these. The same remark applies to the erection of privies which must necessarily cause nuisance, but which, without bye-laws, cannot be controlled until the end which should be avoided has already been brought about.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5659 births and 4176 deaths were registered during the week ending the 26th ult. The annual death-rate in these towns, which had steadily increased in the five preceding weeks from 18·7 to 24·0, further rose last week to 24·9, a higher rate than has prevailed in any week since April, 1883. During the first four weeks of the current quarter the death-rate in these towns averaged 22·7 per 1000, against 23·2, 19·1, and 20·7 in the corresponding periods of 1881, 1882, and 1883. The lowest rates in these towns last week were 11·1 in Brighton, 13·3 in Portsmouth, and 13·8 in Birkenhead. The rates in the other towns ranged upwards to 29·6 in Cardiff, 29·7 in Bolton, 31·9 in Liverpool, and 33·8 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 572, 876, and 1257 in the three previous weeks, were 1246 last week; these included 881 from diarrhœa, 118 from whooping-cough, 86 from measles, 77 from scarlet fever, 33 from "fever" (principally enteric), 30 from diphtheria, and 21 from small-pox. These diseases caused the lowest death-rates last week in Huddersfield and Birkenhead, and the highest rates in Nottingham, Preston, and Leicester. The greatest mortality from diarrhœa, mainly infantile, was recorded last week in Norwich, Leeds, Nottingham, Preston, and Leicester; from measles in Liverpool and Bolton; from whooping-cough in Sunderland and Liverpool; from scarlet fever in Cardiff and Sheffield; and from "fever" in Plymouth. The 30 deaths from diphtheria in the twenty-eight towns included 20 in London. Small-pox caused 23 deaths in Greater London (exclusive of 17 metropolitan cases registered outside Registration London), 1 in Liverpool, 1 in Sheffield, 1 in Hull, and 1 in Sunderland. The number of small-pox patients in the metropolitan asylums hospitals situated in and around London, which had been 1368, 1241, and 1152 on the three preceding Saturdays, had further declined to 1011 at the end of last week; the number of new cases admitted to these hospitals also declined to 105 last week, from 266, 179, and 141 in the three preceding weeks. The Highgate Small-pox Hospital contained 56 patients on Saturday last, 6 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 231, 206, and 177 in the three previous weeks, further declined to 159 last week, and were 26 below the corrected average. The causes of 63, or only 1·5 per cent., of the deaths in the twenty-eight towns last week were not

Digitized by Google

certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, Sunderland, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 21·0 and 22·8 per 1000 in the two preceding weeks, further rose to 23·3 in the week ending the 26th ult.; it was, however, 1·6 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·8 and 18·3 in Perth and Edinburgh, to 24·0 in Paisley and 28·6 in Glasgow. The 563 deaths in the eight towns included 43 which were referred to diarrhœal diseases, 22 to whooping-cough, 6 to measles, 6 to scarlet fever, 5 to diphtheria, 3 to "fever," and not one to small-pox; in all 85 deaths resulted from these principal zymotic diseases, against 87 and 116 in the two preceding weeks. These 85 deaths were equal to an annual rate of 3·5 per 1000, which was 3·9 below the mean rate from the same diseases in the twenty-eight English towns. The deaths attributed to diarrhœal diseases, which had been 13, 32, and 57 in the three previous weeks, were 43 last week, and exceeded the number in the corresponding week of last year by 19; the 43 last week included 25 in Glasgow, 5 in Edinburgh, 5 in Dundee, and 4 in Greenock. The rate of mortality from diarrhœa last week was almost three times as great in the English as in the Scotch towns. The 22 fatal cases of whooping-cough in the Scotch towns showed a decline of 4 from the number in the previous week; they included 15 in Glasgow and 4 in Leith. Of the 6 deaths from measles, 2 occurred in Glasgow and 2 in Dundee. Five of the 6 deaths from scarlet fever and 3 of the 5 from diphtheria were returned in Glasgow; the fatal cases of diphtheria showed a considerable decline from recent weekly numbers. The 3 deaths referred to "fever" included 2 in Paisley and 1 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been but 54 and 66 in the two preceding weeks, further rose to 89 last week, and exceeded by 24 the number returned in the corresponding week of last year. The causes of 69, or more than 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 22·3 and 21·9 per 1000 in the two preceding weeks, further declined to 19·3 in the week ending the 26th ult. During the first four weeks of the current quarter the death-rate in the city averaged 21·1 per 1000, the rate during the same period being equal to 23·9 in London and 17·7 in Edinburgh. The 130 deaths in Dublin showed a further decline of 17 from the numbers returned in recent weeks, and included 16 which were referred to the principal zymotic diseases, against 13 and 24 in the two preceding weeks; 5 resulted from scarlet fever, 4 from diarrhœa, 3 from "fever" (typhus, enteric, or simple), 3 from whooping-cough, 1 from diphtheria, and not one either from small-pox or measles. These 16 deaths were equal to an annual rate of 2·4 per 1000, the rate from the same diseases being 3·3 in London and only 1·7 in Edinburgh. The 5 fatal cases of scarlet fever corresponded with the number in the previous week, while the deaths referred to diarrhœa, "fever," and whooping-cough showed a decline from the respective numbers in the previous week. Four inquest cases and 4 deaths from violence were registered in the city last week; and 30 deaths were recorded in public institutions. The deaths both of infants and of elderly persons exceeded those returned in the previous week. The causes of 20, or more than 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARTILLERY VOLUNTEERS.—4th Lancashire: Edwin Hyla Greves, Gent., M.B., to be Acting Surgeon.—2nd East Riding: Acting Surgeon George Wilkinson Pybus resigns his appointment.—1st Volunteer Battalion, the Leicestershire Regiment: Acting Surgeon Clement Frederick Bryan to be Surgeon.

ADMIRALTY.—The following appointment has been made:—Surgeon Charles William Magrave to the *Penelope*

Correspondence.

"Audi alteram partem."

SIR LYON PLAYFAIR'S ESTIMATE OF "THE WASTE OF THE PROFESSION."

To the Editor of THE LANCET.

SIR,—You ask me how I arrive at the large figure of 1600 as representing the annual demand for licences in the medical profession, or, as I put it, to supply the waste. The word "waste" was perhaps inappropriate, and a few lines further in my speech I used the word "requirements." But my meaning was obvious enough when I said that "the doors of admission to a licence must be wide enough to let 1600 men at least pass through them." If you refer to the minutes of the General Medical Council of March 25th, 1884, you will find that all the licences of corporations and universities amounted to 2163. But a considerable number of these are duplicate entries, on account of men taking more than one licence. I consulted a competent authority, and was informed that 500 would more than correct these double entries. To be on the safe side I deducted 563, and so arrived at, in round numbers, 1600. In your article you show that while the deaths in 1883 were 530, the number of new registries was 1304. As many licentiates go to the colonies and foreign countries, I do not think 1600 very wide of the mark as indicating the number of individual men annually licensed to practise in the medical profession.

I am, Sir, yours, &c.,

London, July 30th, 1884. LYON PLAYFAIR.

*** Sir Lyon Playfair fails entirely to justify his estimate of the waste of the profession, or his attempt to frighten the House of Commons into believing that there was a danger of the supply of medical men falling short of the demand. It is the business of the Medical Registrar to ascertain the deaths of all registered medical men, and, with all his pains, he can only make out an annual death-rate, of—taking the last three years—526. Sir Lyon has told the House of Commons that the waste of the profession is 1600! The annual average number of *new registrations* for the last three years is 1176—that is, *more than twice the number of the deaths.* We must say again that the only thing which Sir Lyon Playfair can properly do with an error which has so grievously misled the House, and so misrepresented the case of the profession, is to make an equally public correction of it.—ED. L.

THE CHOLERA.

To the Editor of THE LANCET.

SIR,—A few days ago my friend, Dr. Wilks, charged me with having discovered Koch's cholera bacillus in 1866, and told me that I had given a brief description of it in the Ninth Report of the Medical Officer of the Privy Council. I disclaimed all knowledge of the fact. Last night, at a meeting of the College of Physicians, he repeated his statement to myself and several other Fellows. I still had to confess incredulity; but determined to look the matter up. This I have just done, with the following result.

In August, 1866, when cholera was raging at the East-end of London, Mr. Simon arranged that a series of investigations should be made into important questions connected with that disease; and he appointed Dr. Wilks, Dr. Martin, Dr. Hughlings Jackson, and myself, to report upon the degrees of success attained by different methods of treatment of cholera, especially as practised in the London hospitals; and Dr. Burdon Sanderson to undertake the verification of alleged experimental proof of the communicability of cholera. Owing to the rapid and almost sudden subsidence of the epidemic, and its limitation in area, the former of these inquiries died in its infancy. Dr. Burdon

Digitized by Google

Sanderson, however, as is well known, was able to repeat and verify Prof. Thiersch's experiments with respect to the communicability of cholera to mice. In the course of his report to the Privy Council, he says: "During the month of September I dissected about twenty mice affected with cholera, more or less severely. During the progress of the inquiry a certain number were forwarded to Dr. Bristowe, who had kindly consented to examine them, and has since furnished me with notes of his observations." And later on, after detailing his own microscopical results, he proceeds as follows: "I append here, by Dr. Bristowe's permission, the notes which have been forwarded to me by him, only observing that the above description"—that is, his own description which preceded mine—"was written before I had read them, and that our dissections were made independently. 'There was in every case a remarkable tendency to decomposition of the bowels. The small intestines generally contained a largish quantity of pale yellowish fluid, mixed with bubbles of gas. The cæcum was more or less distended with fluid of a dusky reddish hue, and similar fluid was also found in greater or less quantity in the colon and rectum. From the anal orifice sometimes mucus and sometimes a little solid lump of fæces was extruded. The fluid in the intestines always contained detached intestinal epithelium, and sometimes an immense quantity of it. The cells were mostly separated from one another, but were sometimes in groups as if they had come off in flakes either from the surface of the mucous membrane or from the interior of follicles. Such cells were met with even in the mucus exuding from the anus. There were also throughout the whole of the intestinal tract vast numbers of low vegetable organisms, some consisting of two joints and undergoing constant movement, others of several successive joints and either moving or stationary (bacteria, &c.)' Dr. Bristowe further refers to 'round or oval well-defined thick-walled cells, apparently parasitic,' which, he says, existed 'in greater or less number in the small intestine, but were always most numerous in the cæcum and large intestine.' He also observed *'numerous oval, slightly curved cells with a single nucleus,'* of the nature of which he is unable to form a decisive opinion. On perusing these forgotten statements of mine, and especially that which I have put in italics, circumstances related with them, but not recorded, came to my mind; and especially I recalled that I had made some sketches of the bodies whose nature I had not ventured to surmise, and on looking for them I found them in one of my note books. Here is an exact reproduction of them. I discovered no memorandum, however, of their actual size or of the magnifying power under which I examined them. But I was working at that time with Ross's highest powers, and was habitually employing lenses magnifying from 500 to 2000 diameters. Probably therefore I drew them as they appeared under a magnifying power of between 500 and 1200 diameters. The bodies clearly accord with my own description of them, and present also the comma-like form manifested by the bacilli which Koch has recently discovered in cholera stools. I think there can be no reasonable doubt that the bodies are in fact identical. Owing to the subsidence of cholera coincidentally with the performance of Dr. Sanderson's experiments, and its absence from England ever since, I never had any further opportunity of investigating the nature of the bodies I described, and none of determining whether or not they were also present in the choleraic evacuations of human cholera patients; and, consequently, although I was evidently interested in them at the time, the incident left no permanent impression on my mind. I need scarcely say that I do not write this letter with the object of putting forward any claim whatever to the discovery of the cholera bacillus. That discovery, assuming it to be one, belongs to Koch alone. But my forgotten investigations seem to me to have a little interest at the present time, inasmuch as they tend to show that Koch's cholera bacilli were found in connexion with the cholera of 1866, and that in Dr. Sanderson's experiments cholera, as was at the time contended, was actually imparted to mice. They show, too, how closely one may approach a discovery and yet fail to grasp it.

I am, Sir, yours faithfully,

Old Burlington-street, July 23rd, 1884. J. S. BRISTOWE.

To the Editor of THE LANCET.

SIR,—Perhaps at present a few simple facts concerning cholera may prove instructive. They came under my notice while serving in India, through two very virulent epidemic invasions—one at Delhi in June, 1861, another at Jullundhur in September, 1862, while surgeon to H.M.'s 82nd Regiment. Both outbreaks emanated from the enormous gatherings of religious pilgrims who periodically flock to the "holy city" of Benares, and, dispersing thence, carry back the *materies morbi* (indigenous to the place), leaving its footprints, march by march, along the various routes they retrace homewards. Thus it reached Delhi, where the 82nd Regiment was quartered after the Mutiny, not in barracks, but in native buildings extemporised for use in the city, and within the fort, both these being separately enclosed within lofty fortified walls; the latter inside the former. I need scarcely say the sanitary condition was indifferent. The men in the fort suffered more severely than those in the city around, but the band, some forty strong, which occupied the worst quarters of all—viz., an old zenana building, crowded and closely shut in from light and ventilation by high thick walls absorbing and radiating heat—had not a single case from first to last. The companies in the fort, the most severely attacked, were moved (in June) to tents on "the ridge," a belt of slightly elevated ground not more than half a mile from the city. The disease ceased at once; not another case occurred. Other companies were sent in detachments to the Kootuli and elsewhere; the change was also beneficial, and disease slowly abated. Three men occupied a small central room or compartment open on four sides to the Martiniere building. All three died in two days, the adjacent rooms being free; one man was taken from the room to the hospital, the two others on duty returned to the room and died next day. No special local cause was ascertainable. Delhi boils and Delhi flies were the whole time as pestilential as usual. At Jullundhur the barracks are separated by a road; on one side the disease was virulent and fatal, on the other side absent. This epidemic was extremely virulent in type, though limited in extension, the regiment being at once broken up into detachments and kept moving every few days. It lasted from September 8th to the 21st; all, or nearly all, attacked died. Various methods of treatment were adopted: calomel, quinine, effusion, electricity, opiates, stimulants, counter-irritants, heat, &c.; all failed. Prognosis was mere guesswork. Some of the worst cases (inveterate drinkers) recovered when in articulo mortis; others more favourably circumstanced, especially among the women, proved fatal. My own opinion is, I am sorry to own, that in types of this virulence medical science has as yet no remedy whatever.

I am, Sir, your obedient servant,

Bedford, July 29th, 1884. H. D. FOWLER, Deputy Surg.-Gen., A.M.D. (retired).

P.S.—How is the cholera bacillus (?) so suddenly annihilated and so definitely limited? Should not the use of rain water as much as possible be substituted for that in ordinary use during cholera times? No officers or members of their families suffered; they were quartered both in the fort and city of Delhi outside, and the same applies to Jullundhur.

To the Editor of THE LANCET.

SIR,—Now that the subject of Asiatic cholera is again upon the *tapis*, perhaps the synopsis of a hundred cases treated during the present outbreak at Marseilles may be of interest to you. I may premise that, taken as a whole, the present epidemic cannot compare in virulence with those which devasted various English towns in 1849. The percentage of those attacked and the mortality among them are both much less. Out of the total of 100 cases, 10 died of the fatal cases, 2 died before there was time for symptoms of reaction to manifest themselves; 1 died of exhaustion produced by diarrhœa and vomiting, after an illness of varying duration, but under three days. Five died after an illness protracted beyond the three days, but

from the same cause—viz, asthenia produced by exhausting discharges; 2 died of consecutive fever. The cases coming under the first category ended fatally in from five to twelve hours. Their aspect was appalling to anyone not accustomed to such sights. The eyes were sunk in the back of the head like those of a corpse, but widely opened and staring; eyelids livid; skin of an ashen-grey colour, cold and clammy with moisture; the features were often so distorted as to be unrecognisable by the nearest relations; the pulse was imperceptible. The patient often shrieked aloud to the "bon Dieu" or to his or her favourite saint. The limbs were violently cramped and the whole aspect that of acute suffering and collapse. Those who survived this stage to succumb at a later period presented the usual symptoms, which have been sufficiently described in medical works. The only point to which I desire to draw attention is the greater proportion of cases which, though ultimately fatal, survived beyond the third day as compared with the percentage recorded in previous epidemics. This may be either due to the milder character of the virus or to the greater efficiency of the treatment. Only one death among medical attendants has come to my knowledge, that of a student, with whom I was well acquainted; so perhaps, after all, the Duc de Chartres in his recent act of heroism did not run any very great risk.—I am, Sir, yours truly,

ALFRED DRYSDALE, M.B. Lond.,
Officier de Santé.

Mentone, July, 1884.

THE WELDON CASE.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to state that I am not the defendant in the recent trial, Weldon *v.* Semple, and that I know nothing of the case beyond what I have read in the newspapers.—I remain, Sir, yours very truly,

R. H. SEMPLE, M.D., F.R.C.P.L.

Torrington Square, July 31st, 1884.

THE SANITATION OF MARSEILLES HARBOURS.

To the Editor of THE LANCET.

SIR,—Your Liverpool correspondent, in commenting upon the cases of cholera on board the steamship *St. Dunstan* in the current issue of THE LANCET, says:—"It transpired that the vessel was put into a dock into which a portion of the sewage of Marseilles was discharged, and the men noticed, particularly at night, a strong and offensive effluvium." I have to observe that the same thing was noticed by myself and other passengers of the Peninsular and Oriental steamship *Cathay*, which entered the quarantine harbour at Marseilles on March 25th. Moreover, the water being quite still, large quantities of excreta could be seen floating about in the early morning, and the stench was abominable. We had to undergo the stupid, absurd, and odious *fiasco* of quarantine, which was enforced for twenty-four hours, while the *Cathay* and other vessels were exposed to the influence of the effluvium of sewage, which, it would appear, was pumped into the quarantine harbour for some occult purpose. We were boarded by officials; an *officier de santé* inspected the crew and officers, but not the passengers; and, during a long interview with the ship's surgeon, he put that gentleman through a searching *vivâ-voce* examination on the symptoms of cholera, and the differential diagnosis between it and dysentery. He caused the hatchways to be limewashed, and the w.c.'s of the native crew only to be nominally disinfected. From Paris I sent a report on the bad sanitary arrangements at Marseilles and the danger of cholera for publication in your columns, but it would seem that the manuscript did not reach its destination.

I am, Sir, yours, &c.,

JOHN C. LUCAS.

July 28th, 1884.

FOREIGN GRADUATES' ASSOCIATION.—Dr. W. C. Dansie, of Epsom, has been elected President for the ensuing year, vice Dr. H. J. Handwicke, of Sheffield, who becomes a Vice-President. Dr. K. N. Macdonald, a former President, has been elected a Vice-President, and Dr. J. J. Bailey, of Marple, Hon. Secretary. The Council consists of twelve London and provincial foreign graduates.

NEWCASTLE-ON-TYNE.

(*From our own Correspondent.*)

THE ROYAL VISIT TO NEWCASTLE.

HIS Royal Highness the Prince of Wales with the Princess and some of the Royal children are expected to arrive here on August 19th, and will at once proceed to Sir W. Armstrong's seat at Rothbury, where they will stay during their visit to Northumberland. The next day they will visit Newcastle to open the new building erected for the Natural History Museum and the Jesmond Park, presented to Newcastle by Sir W. Armstrong. The new reference department of our public library will also be opened, and the day's proceedings will conclude with a banquet given by the civic authorities to the Prince, which is expected to be a representative one, and worthy of the occasion. The next day the Prince will again visit the city, and, taking a view of the Tyne and the famous High Level Bridge, will proceed down the river to North Shields, and after opening the new dock there will go on to our "Northern Brighton," Tynemouth. Thence he will return to Rothbury, and possibly have a few days' grouse shooting in the vicinity, the place being surrounded by well-stocked moors. It has given much satisfaction that the Royal party is to be welcomed and received in our ancient town, but modern city, by a medical mayor (Mr. H. W. Newton).

ROTHBURY.

The Royal visit will bring this picturesque little mountain town into deserved prominence, so that a few words about it as a health resort may not be out of place here. Rothbury, the name of which signifies "the town in the clearing," is situated forty-one miles from Newcastle. The town has a population of rather over 5000, and has been known as a health resort for several generations. The beautiful valley of the Coquet, on which it is situated, extends from three to four miles, and is about two miles broad. The main street is about 250 feet above the sea-level, and the valley is shut in on all sides, except the west, by hills from 700 to 1400 feet in height; ample protection is thus given the town from all cold winds. Observation shows the rainfall to be moderate; but what is of far more consequence is the fact that this rainfall occurs on about 160 days, the remaining 205 being quite dry. Dr. J. Gordon Black, of Harrogate, who has given much attention to the climate of Rothbury, says that sufferers from spasmodic asthma or chronic bronchitis with asthma should carefully avoid the place, from its air being a too powerful and exciting a stimulant. In pure bronchitis, however, having a tendency to become chronic from passive congestion of mucous membrane, Rothbury is often curative by exciting a healthy circulation. For strama no better inland or rather mountain health resort could be selected. The drinking water is pure and soft, and, as Dr. Gordon Black observes, admirable as a means of solution of thickenings or coagulations of the lymphatic type. It may be mentioned that the Coquet is celebrated as the *beau idéal* of an angler's river; and that the trout streams are numerous and well stocked. The little town will supply all the wants of the visitor. Lodgings are good, and as yet the charges are moderate; but during the present season, which is an exceptional one owing to the Royal visit, visitors would do well to make arrangements as to quarters in advance.

Newcastle-on-Tyne, July 28th, 1884.

IRELAND.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE election for a Professor of Surgery in the Medical School of the College took place on the 24th ult., when, after an exciting contest, Mr. Edward Hamilton was successful. Of eighteen members of Council who recorded their votes, ten voted for Mr. Hamilton and eight for Mr. Corley. The result has been, as I anticipated in these columns some time since—viz., the election of Mr. Hamilton by two or three votes. Either candidate was well qualified to succeed the late Dr. Stannus Hughes in the chair of Surgery. The election of Dr. Cameron to the Vice-Presidency necessarily

Digitized by Google

causes a vacancy for a member of Council, which will be filled up on Monday, the 4th inst. So far there are only two candidates before the electors—Mr. Corley (late Vice-President) and Mr. Nixon. At the recent examinations for the first half of the licence in Surgery, of seventy-four candidates who presented themselves only twenty-six satisfied the examiners.

PRECAUTIONS AGAINST CHOLERA IN BELFAST.

The committee appointed to make proper arrangements should cholera visit that town recently met to consider the report of Dr. Seaton Reid in reference to the staff and accommodation required at the intercepting hospital. They recommended that nurses and a medical staff should be engaged, and that an additional building be erected near the present intercepting hospital, to contain ten additional apartments. These suggestions came before the guardians last week, who agreed to the various recommendations made except as regarded the additional building, which was considered unnecessary. The guardians, however, have taken advantage of an offer made through the Local Government Board to utilise a number of police huts capable of accommodating five or six persons each.

SANITARY CONGRESS IN DUBLIN.

A Sanitary Congress and Exhibition will be held towards the end of September, under the auspices of the Sanitary Institute of Great Britain. Various papers will be read and discussed on matters relating to sanitary science. There will be three sections—viz., Sanitary Science and Preventive Medicine, presided over by the Registrar-General for Ireland; Engineering and Architecture; and, lastly, Chemistry, Meteorology, and Geology, of which the President will be Dr. Cameron, Vice-President of the Royal College of Surgeons. The special questions in the various sections include the housing of the poor, the disposal of town sewage, and the effects of water-supply and of site and climate on health. Dr. Cameron is expected to read a paper on the influence of good water supplies on health considered from a chemical and physiological point of view.

ROYAL UNIVERSITY OF IRELAND.

The Maternity Hospital, Glasgow, and the Maternity in connexion with the Royal Infirmary School of Medicine, Liverpool, have been placed on the list of institutions from which the University receives certificates for degrees in medicine.

It is proposed to hold a Hospital Saturday in Belfast, to benefit the funds of the Belfast Royal Hospital.

During the June quarter there were 31,549 births and 23,868 deaths registered in Ireland, the births and deaths being both below the average. Compared with those for the corresponding quarter of 1883, the returns of pauperism show a decrease of 2888 in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 3483 in the number of persons on out-door relief.

Dublin, July 29th, 1884.

PARIS.

(From a Correspondent.)

THE CHOLERA.

In hinting last week that the diversity of opinions expressed by those who consider themselves authorities on the subject would not be without an injurious effect upon the public, I did not anticipate so speedy a confirmation of my words. In several instances those who have been seized with cholera have committed suicide upon feeling the first symptoms, rather than take their chances of treatment, and now a newspaper correspondent telegraphing from Marseilles on July 26th says, "A medical certificate bears the following statement: 'The patient refused to take the medicine prescribed, and, although the fact has only been officially noticed to-day, certain patients have refused for the last few days either to see a doctor or take medicines.'" And not without some reason. Every theorist must thrust his ill-digested views on the public through the medium of the daily papers, and so the newspapers are filled with the most contradictory statements, which cannot fail to destroy anything like confidence. One considers the alkalinity of the secretions the great thing to be got over, and would saturate the patient with acid to check the development of bacilli. Another considers these of so little importance that he would swallow any amount of them to prove it. I am not alluding to the opinions expressed in the medical press, where, of course, they are entirely in place, but to the letters with which the lay periodicals are crowded. Another enthusiast writes on the virtue of copper *intus et extra*, and others must do battle for and against astringents. The homœopaths, too, are claiming to be consulted. One of their adepts would have the choleraic patients handed over to them exclusively on the ground that, whereas the death-rate is only 20 per cent. in their hands, thrice that mortality results from allopathic treatment. If certain members of the medical profession are enjoying the satisfaction of seeing their lucubrations in print, the chemists and manufacturers of cholera specifics and quackeries are reaping more substantial advantages. The copper theory has been appropriated by an enterprising individual, who makes a kind of plaster, a certain surface of which is guaranteed to secure immunity from cholera during the next twenty-four hours; each day the application must be repeated, and the greatest benefit (to the vendor) of course results from the application. Another external appliance of occult power which has been largely advertised as a cure for every kind of pain, and, strange to say, at the same time as a remedy for locomotor ataxy and obesity, this last affection being radically cured in thirty days, is now asserted to stay the virulence of cholera. The advertisers ingeniously admit that it will not preserve from the disease, but its pain-allaying qualities of course render the malady less formidable. The specifics for internal use, both of home and foreign manufacture, are advertised in the most unwarrantable manner, too often owing much of their success to medical encouragement; and to give some idea of the extent to which ill-advised medical advice and pharmaceutical quackery is carried, it may be mentioned that on Monday last the secretaries of the Academy of Sciences received no less than *two hundred and forty* communications on the subject. M. Gosselin, speaking in the name of the Commission appointed to examine this correspondence, informed the Academy that there was nothing in it of any practical interest. Some of the writers had medicines with which they wished to experiment without allowing the composition to be known; others offered to sell their "secret" to the Government for various large sums. There were those who wanted to contract at so much per cent. either with the Government or with the patients. And, lastly, came experimenters claiming that wards should be reserved for them in the hospitals to try the various remedies they fancied; amongst these were olive oil, sulphur, petroleum, benzine, carbolic acid, baths of urine (!) and of wine, arsenic, copper, veratrin, pilocarpine, salicylic acid, inhalations of oxygen, &c. Surely there never was better proof of the advisability of suppressing quack medicines altogether. If any of these preparations are really useful in cholera their composition should be made known, and the profit derived from their sale reaped in a regular manner by the retailers; but at the present time the medical profession especially should set its face against this speculation in human life by inventors of secret medicines, and discourage every such speciality, however vaunted by the advertisers. The mortality from the epidemic during the last week in the principal centres has been as follows:—

Date.	Toulon.	Marseilles.	Arles.

July 30th, 1884.

ROYAL VISIT TO ST. THOMAS'S HOSPITAL.—Her Imperial Highness the Crown Princess Victoria of Germany and suite visited St. Thomas's Hospital on Tuesday afternoon at very short notice, with a view to seeing the hospital in its every-day working state and under ordinary conditions. Her Imperial Highness visited several of the wards, the various details connected with the working and nursing arrangements being explained to her by the senior surgeon, Mr. Sydney Jones, Dr. Hadden (on behalf of the medical staff), and Mrs. Wardroper, the matron of the hospital. At the close of her visit the Crown Princess expressed her satisfaction with the arrangements of the institution.

ROYAL COLLEGE OF PHYSICIANS.

At the ordinary Comitia, held on Thursday, the 31st ult., Sir W. Jenner, Bart., President, in the chair, the following gentlemen were elected censors for the ensuing year—Dr. J. W. Ogle, Dr. Wilson Fox, Dr. W. H. Stone, and Dr. J. E. Pollock. The examiners and other officers were also appointed.

The report of the Cholera Committee, embodying general instructions for the prevention and treatment of cholera, was received, and will be published after it has been sent to the Local Government Board.

Reports from the Library Committee, the Curators of the Museum, and the Finance Committee were read and adopted.

The Medical Bill having been withdrawn, a committee was formed to facilitate the adoption of the Scheme for a Conjunction of the College with the Royal College of Surgeons for examination purposes.

MEDICAL NOTES IN PARLIAMENT.

Smoke Abatement.

IN the House of Lords on Monday, Lord Derby presented a petition from the vestry of St. James's against the Smoke Abatement (Metropolis) Bill.

On Thursday, Lord Stratheden and Campbell moved the second reading of the Bill, and it was carried by 31 to 17, but on the understanding that at this period of the session the measure would not be enabled to pass into law.

The Canal Boats Act Amendment Bill and the Cholera Hospitals (Ireland) Bill passed through Committee.

Oleomargarine.

In the House of Commons, on Friday (25th ult.), Mr. Hibbert informed Mr. Duckham that the Local Government Board had no supervision over oleomargarine factories, and had no definite information as to the extent of the manufacture in the United Kingdom. They believed the provisions of the Food and Drugs Act were sufficient to meet the case of any deleterious compound, and a circular was sent to the sanitary authorities last month, urging increased activity in obtaining samples of food and drugs for analysis. If samples of oleomargarine were found to be injurious to health, and if that compound were sold when butter was asked for, prosecutions would follow, as they had in the case of butterine.

The Medical Bill.

In reply to Mr. Talbot, Mr. Gladstone expressed his regret at having to announce that in view of the convenience of members and the circumstances of the session, this Bill would not be further proceeded with this session. Subsequently, the order for going into committee was discharged, and the Bill was withdrawn. During the week, petitions in connexion with the Bill continued to be presented, mostly in favour of the proposed Pharmacopœia Committee.

Rags and Cholera.

Sir C. Dilke assured Sir F. Milner that a cargo of rags from Marseilles had not been landed. In reply to Mr. Cowen, the right hon. baronet said there was no evidence of the communication of cholera by rags, but small-pox and woolsorters' disease had been so conveyed.

The Carriage Tax.

Lord A. Percy moved a resolution in favour of the abolition of the carriage tax, and specially referred to medical men as requiring carriages for professional purposes. The Chancellor of the Exchequer contended that several other taxes had priority for remission, and the resolution was rejected by 93 to 38.

Broadmoor Lunatic Asylum.

In Committee of Supply, Mr. Hibbert informed Mr. Warton that the increase of 7 per cent. in the vote for this asylum was due to the fact that criminal lunatics were no longer sent to licensed houses.

Vaccination Questions.

Mr. Russell replied to Mr. Hopwood that the death of a recently vaccinated child, named Best, at Hull, was certified as due to erysipelas, and the doctor stated that the disease had no connexion with the vaccination. Other children vaccinated from the same lymph took no harm. The parents asked the Local Government Board for an inquiry, but at present no action had been taken.

On Tuesday, Mr. Russell stated to the same hon. gentleman that the Local Government Board did not propose to sanction the stipulation of the Dewsbury guardians, that a public vaccinator should guarantee children against injury. The present rules were sufficient to prevent any but the most minute risk, and a public vaccinator ought not to be called upon for more than due observance of these rules.

The State of the Thames.

On Monday, Sir W. Harcourt, in answer to Mr. Rogers, said the correspondence between the Home Office and the Metropolitan Board of Works on this subject would be ready for presentation next week.

Burgh Police and Health (Scotland) Bill.

A petition from the Forfarshire Medical Association was presented against the Bill.

On Tuesday, the rejection of the Bill was moved by Mr. Hopwood, who strongly complained of the arbitrary powers proposed to be given by it to local sanitary authorities. A long debate followed, and after a division the House went into committee on the Bill, but progress was immediately reported, and it is understood that the Bill cannot pass this session.

The Contagious Diseases Acts.

In Committee of Supply on the Army Estimates, Mr. Puleston raised a discussion as to the evil effects of the abolition of compulsory examination. Dr. Farquharson, whilst admitting that the Government were bound to act upon the adverse vote of the House of Commons, said the Acts must fail without compulsory examination. He praised the manner in which the doctors and police had performed their duties. Lord Hartington averred that he was still opposed to the step which had been taken, but he did not regard the consequent increase of disease as considerable. Mr. Campbell-Bannerman endorsed this view with regard to the navy. Lord Hartington excused the non-production of his promised Bill owing to the state of public business.

The Lunacy Laws.

On Thursday, in reply to Sir H. Holland, Lord E. Fitzmaurice stated that much information as to the lunacy laws of foreign countries was to be found in a book by Dr. Harrison of Philadelphia, entitled "Legislation for Insanity." He should be happy to show the hon. member a copy, and to procure further information if required.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following candidates passed the Second Examination in Anatomy and Physiology on July 25th:—

Alfred Percy Blankinsop, Henry Asher Dutch, Frederick Richard Miller, Wm. Arthur John Nottingham, John Maynard Picktball, Ernest Albert Qaicke, Alfred Henry Spurrier, George William Stringfield.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 24th ult:—

Aikins, Henry Wilberforce, M.D. Toronto, Toronto.
Biden, Charles Walter, L.R.C.P. Lond., Peckham.
Bolton, John Usherwood, L.R.C.P. Edin., Wimbledon.
Coronel, Julius, M.D. Amsterdam, West Indies.
Craddock, Sidney Ernest, L.S.A., Milman-street.
Gooding, Charles Ernest, M.D. McGill College, Barbadoes.
Loring, J. Brown, M.D. McGill College, Montreal.
Macdonald, George Childs, L.R.C.P. Ed., Craven-street.
Marriott, Hyde, L.S.A., Stockport.
Miller, Thomas Hugh, L.R.C.P. Lond., Clapham.
Morgan, George, L.S.A., Brewer-street.
Parrott, Thomas Godfrey, L.R.C.P. Lond., Aylesbury.
Penny, Francis, L.S.A., Crewkerne.
Perkin, R. F. Thornton, Warwick.
Rees, William Thomas, L.S.A., Llanboidy.
Reilly, Charles Cooper, L.R.C.P. Lond., Denbigh-street.
Rowell, George Ball, M.D. McGill College, San Francisco.
Shaw, H. C. Costello, L.R.C.P. Lond., Kingston-on-Thames.
Watson, James Russell, L.S.A., Moore-street, Chelsea.

Admitted Members of the College on the 25th ult.:—
Barker, A. J. Glanville, Finsbury-park.
Collins, W. C. Glasier, L.R.C.P. Edin., Holford-square.
Drage, Lovell, Hatfield, Herts.
Harpur, Alexander, Hertford-street, Mayfair.
Innes, Charles Barclay, Hampstead.
Laslett, Thomas George, L.R.C.P. Lond., Bootle, Lancashire.
Macloglin, E. P. Plantaganet, Wigan.
Purslow, Charles Edwin, Wolverhampton.
Somers, Edward O'Reilly, Salford.
Spry, William, Southsea.
Stevenson, John, L.R.C.P. Lond., Stretford, Manchester.
Watkins, Arthur Muriel, L.R.C.P. Lond., Newton-le-Willows.
Webster, Ernest, Hulme, Manchester.
Wild, George Samuel, Liverpool.
Williams, Patrick Watson, Bristol.

Admitted Members of the College on the 28th ult.:—
Adie, Joseph Rosamond, Brixton.
Aikin, William Arthur, Clifton-place.
Barber, Frederic Samuel, Claremont-square.
Brock, J. H. Ernest, Bartholomew-road.
Brogden, Richard William, L.R.C.P. Lond., Clapham-road.
Castor, Richard Henderson, L.R.C.P. Lond., Primrose-hill.
Montbrun, Pedro Louis de, L.R.C.P. Lond., Trinidad, West Indies.
Reid, A. St. George Cauldfield, Chatham.
Roberts, James Reid, L.R.C.P. Lond., Suez, Egypt.
Ruck, John Ernest, Devizes, Wilts.
Stacy, W. H. Waterhouse, Norwich.
Turner, Philip Dymock, Tulse-hill.
Voelcker, Arthur Francis, Argyll-road.

Admitted Members of the College on the 29th ult.:—
Cocking, William Tusting, Sheffield.
Elliott, John, Whitchurch, Salop.
Field, Adolphus Theodore, L.S.A., Shepherd's-bush.
Fowler, Alfred Henderson, L.R.C.P. Lond., Sharsted-street.
Gabriel, William Maurice, Gloucester-gardens.
Habershon, Samuel Herbert, Brook-street.
Hall, Alfred Richard, Stanraer-place.
James, John, Llangwyryfon.
Lavie, Tudor German, Queen Anne's-gate.
Morgan, T. W. Sewell, L.S.A., Roupell-park.
Penrose, Francis George, Gower-street.
Roberts, Owen William, L.R.C.P. Lond., Cambridge-gardens.
Smith, E. A. Cloete, L.R.C.P. Lond., Woolwich.
Taylor, Alfred Ernest, Acton.
Tubby, Alfred Herbert, Kennington.
Vernon, J. J. Dean, Audley, Newcastle-under-Lyne.

Admitted Members of the College on the 30th ult.:—
Andrews, Charles, Hammersmith-road.
Fouterton, A. G. Russell, Norland-square.
Gayford, Charles, Brecknock-road.
Hornby, Thomas Edmund, Mile-end.
Jackson, Percy Vaughan, Ballina, county Mayo.
Muspratt, Charles Drummond, Clapham.
Palmer, Sydney Joseph, Seaton, Devon.
Pearse, Frank, L.R.C.P. Ed., Exeter.
Randell, R. M. Henry, Sydenham.
Spreat, Frank Arthur, Belsize-square.
Washbourn, William, Blackfriars, Gloucester.

[In the list published last week the name Frederick Bryden, M.B. Melbourne, should have been Frederick Bryan, M.B. Melbourne, Australia.]

COLLEGIATE FINANCES.—From the last annual report, just published, of the receipts and expenditure of the College in the year ending Midsummer-day last, it appears that the former amounted to £20,024 5*s.*, derived principally from fees paid on examinations for the Fellowship and Membership of the College, which produced £16,917 7*s.*; fees paid on admission to Council, Court of Examiners, and to Fellowship, £94 10*s.*; dividends on stock and rents from chambers adjoining the College, £2713 17*s.* 3*d.* The disbursements amounted to £20,046 7*s.* 4*d.*, the largest item being in fees paid to the Council and members of the Court and Board of Examiners—viz., £7674 4*s.* The next largest item was for salaries and wages for the officers and servants in the three departments, office, museum, and library—viz., £3784 14*s.*; taxes, rates, diploma stamps, and insurance, £1469 9*s.* 3*d.*; miscellaneous items, £441 11*s.* 6*d.* In the extraordinary expenditure, £700 appears in honoraria to Messrs. Trimmer, Goodhart, and Doran; leaving a balance at the bankers of £2065 3*s.* 5*d.*

THE HUNTERIAN MUSEUM.—In his interesting annual report on the state of the Museum, Professor Flower states that an unusually large number of specimens have been added to the Pathological section. The series of Diseases of the Teeth, previously small and incomplete, have received an addition of 130 specimens, collected from various sources, many of them presented by Mr. Alfred Coleman, F.R.C.S. Among other notable contributions was a very valuable specimen of actinomycosis, affecting the lower jaw of a heifer, and two examples of the same disease of the tongues of oxen, which were presented by Mr. Alfred Lingard. Upon the conclusion of his course of lectures on the Surgery of the Urinary Organs, Sir Henry Thompson presented to the Museum the cabinet containing his collection of calculi, the result of 812 operations by lithotrity and lithotomy, which has been already noticed. Among valuable additions to the series of Human Osteology, Prof. Flower specially mentions a series of skulls and skeletons of natives of Sierra del Fuego, presented by the Rev. Thomas Bridges, of the South American Missionary Society.

UNIVERSITY OF EDINBURGH.—The following candidates have passed the final examinations. Those marked thus * have passed with distinction:—
A. M. Adams, M. S. P. Aganoor, N. E. Aldridge, J. H. L. Allott, M. Altounian, S. Arnold, E. H. Bannister, J. Barrie, G. B. Batten, J. B. Bawden, T. W. Bell, D. Berry, *A. Bissett, J. A. Blair, F. M. Blumer, B.A., T. Bonar, F. F. Bond, J. E. Bottomley, *P. Bowes, H. Bramwell, H. R. Bramwell, R. A. Brewis, *D. M. Brown, *R. M'D. Brown, T. A. Brown, S. B. Burns, J. M. Cadell, E. K. Campbell, *E. Carmichael, W. R. Carter, L. M. F. Christian, T. G. Churcher, R. L. Clark, D. Cloete, J. G. Cossins, R. S. Coulthard, A. H. Croucher, W. L. Cullen, A. S. Cumming, T. B. Darling, H. H. Davies, T. L. K. Davies, J. D. Davies, T. W. Dewar, *D. G. Donaldson, D. R. Dow, M.A., T. Easton, M.A., E. Eckersley, T. Edwards, H. S. Fairbank, J. E. A. Ferguson, J. H. Ferguson, T. Ferrier, G. Fisher, W. S. Flett, A. Fraser, T. Fraser, M.A., T. A. W. Fulton, C. H. Gage-Brown, W. G. Gallelly, D. J. Galloway, D. F. Gardiner, L. R. Gray, F. G. Greenbury, E. Greenough, B. Griffiths, C. D. G. Hailes, *W. W. Hall, J. R. Henderson, T. M. Hodgson, W. A. Holmes, T. A. F. Hood, *R. Howden, R. S. Hubbersty, Dirk de Vos Hugo, J. Hume, B. E. Iastrzebski, J. O. Jones, G. H. Kenyon, M. A. Ker, D. O. Kerr, J. Kerr, W. V. M. Koch, D. Laing, W. Laing, C. A. Lane, *W. S. Lang, A. E. G. Langschmidt, C. N. Lee, A. W. M. Leicester, L. H. Le Merle, C. L. Lempriere, W. G. Little, M.A., G. S. F. Loubser, W. W. R. Love, C. J. Macalister, B. F. P. M'Donald, A. G. Macdonald, W. C. M'Ewan, M.A., J. M'Gibbon, A. MacGregor, D. MacGregor, M.A., H. J. Mackay, W. B. Mackay, J. C. Mackenzie, *J. H. Mackenzie, M.A., M. MacLaren, B.A., A. Maclennan, J. M'Leod, B.A., J. M'Myn, A. Macqueen, G. D. Malan, L. G. Mallam, A. Matheson, A. Menzies, W. J. van der Merwe, G. Michael, R. Mitchell, M.A., D. Morgan, A. E. Morison, D. Mowat, W. J. Munro, B.A., F. Morgan, B.A., B. H. Nicholson, J. Noble, F. B. O'Flaherty, *A. G. Paterson, M.A., C. E. Paterson, *F. A. Pockley, J. M. S. Preston, E. F. T. Price, W. T. Prout, A. C. Purchas, T. R. Rait, *F. M. Reynolds, T. Rhodes, W. Richards, J. Rigg, A. L. F. Robertson, J. Robertson, J. C. Robertson, R. M. Robertson, A. J. T. Roux, J. Rutter, Y. S. Sanitwongse, T. S. Shaw, *F. H. Simmons, G. R. Smuts, W. Sneddon, J. S. Stephen, H. F. D. Stephens, S. H. A. Stephenson, *J. Stevens, M.A., C. H. Stewart, B.Sc., J. W. Stirling, J. Stuart, G. H. H. Symonds, J. C. Taylor, G. Thomson, R. S. Thornton, C. G. Thorp, J. Tod, Cecil G. Traill, George A. Tullis, J. W. O. Underhill, E. Walker, N. H. Walker, N. P. Walker, D. Wallace, T. A. Watson, S. F. Wernich, A. Westlake, R. H. A. Whitelocke, W. J. Will, *C. Wilson, A. B. Winder, J. E. Wolfhagen, J. C. Young, B.Sc.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations held on July 14th and following days, the undermentioned were admitted Licentiates of the College:—
Arthur J. Barlow, Henry T. Baylor, George Brown, William J. Connor, John J. Costello, Samuel A. Crotty, Robert Cross, George Davidson, Henry G. Day, Ulysses C. H. De Burgh, William Dillon, Joseph E. Dormer, Andrew A. Doyle, Alexander T. Drake, Fitzwilliam Evans, Charles J. Falkner, Martin Fennelly, Richard H. Fetherston, Robert Gloster, William E. Grandy, John Hobbs, Samuel Horneck, William G. F. Johnston, Cornelius J. Kelly, Patrick J. Kiernan, Alexander D. La Touche, Edmund D. La Touche, Richard R. Leeper, Kenneth Mackay, Michael J. Magan, Barcroft Manly, Robert F. McArdle, Arthur McCutcheon, John J. McDonnell, John McFadden Arthur McGaman, John McGrane, Henry McLaughlin, William McManus, Hugh Morrison, Timothy Mulcahy, Edwin G. Newell, John J. Norton, James Oakly, Alfred Ross, James L. Rowlette, Francis H. Sinclair, Alfred J. Smith, James H. Stewart, Augustus Tabuteau, Hamilton J. Thornbury, Launcelot A. Whitcroft.

APOTHECARIES' HALL.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 24th:—
Field, Adolphus Theodore, Sunnyside, Shepherd's-bush.
Hall, William Hall, Cumberland-park.
Lewis, James King, Old Woolwich-road.
Pollard, George Frederick, Earl's-court-road, Kensington.
Silverlock, Richard Greenhill, Northwold, Norfolk.
Vallance, Ernest, The Deanery, Stratford.
Warwick, Francis Jas., Vaughan-road, Loughborough.

THE Chelsea demonstration in aid of the Victoria Hospital for Children realised £237 6*s.*, as compared with £105 collected last year.

AN official inspection of the Thames from Westminster to Erith, on behalf of the Metropolitan Board of Works, has been made by Dr. Dupré and other experts.

A NEW Eye Hospital was opened at Birmingham on the 24th ult. The cost of the building and appliances is estimated at £20,000.

AT the examination in Diseases of Women held at the Hospital for Women in July, the first prize was awarded to Mr. J. R. Jones, of University College Hospital, and the second prize to Mr. Barber, of St. Bartholomew's Hospital.

Digitized by Google

THE Congress of German Naturalists and Physicians will be held at Magdeburg, Sept. 18th to 23rd.

A NEW Masonic Lodge, which was consecrated at Waltham-cross on the 23rd ult., has been named the "Wilson Iles Lodge, No. 2054, in memory of the late Bro. F. H. Wilson Iles, M.D., of Watford.

BRITON LIFE ASSOCIATION.—The annual report of this Association was presented to the general meeting of shareholders and policy-holders on Thursday, the 17th ult. The premium on new business (£5253 19*s.* 3*d.*) is in excess of the previous year. A dividend of 5 per cent. was declared, and the funds increased to £54,396 15*s.* 7*d.* We would again call attention to the advantages offered by this Company to insurers who are total abstainers from alcohol.

THE FISKE FUND PRIZE.—At a meeting of the Rhode Island Medical Society on June 19th, it was stated that a prize of $300 for the best essay on "The Origin and Progress of the Malarial Fever now Prevalent in New England" had been awarded to Dr. C. V. Chapin, the Superintendent of Health of the City of Providence. The following subjects were proposed for the year 1885: "Original Investigations in Household Hygiene," "The Present State of the Germ Theory of Disease," "Physiological and Pathological Effects of the Use of Tobacco," "Migraine, its Nature and Treatment." The prize for the best essay to be $200.

THE SALOP AND NORTH WALES EYE, EAR, AND THROAT HOSPITAL. — The sixty-fourth annual general meeting of the subscribers to this institution was held on the 23rd ult. During the past year 153 in-patients have been received and 1139 out-patients attended, making a total of 1392. Only fourteen beds have hitherto been provided, but the committee hope during the present year to supply the full complement—viz., twenty. The total receipts during the year were £1814 6*s.* 8*d.*, and the expenditure £1787 12*s.* 9*d.*, leaving a balance of £26 13*s.* 11*d.* in favour of the hospital.

VACCINATION OFFICERS' ASSOCIATION. — The monthly meeting of this Association was held on the 19th ult., at the Charing-cross Hospital Medical School. It was resolved that each member of the Association be requested to furnish the secretary with the following information:—1. To show how promptly on the action of the vaccination officer the protection of vaccination can be secured to those in infected houses. 2. Any instances in which such prompt action has illustrated its advantages. The thanks of the Association were also expressed to the National Health Society for the pamphlet issued by them calling the attention of the public to "Facts concerning Vaccination."

ST. JOHN AMBULANCE ASSOCIATION.—A conference of the London and provincial medical staff was held on Friday, the 25th ult., by permission of the council, in the theatre of the Royal United Service Institution, for the purpose of discussing points connected with the instruction and examination of classes. Dr. Sieveking presided, being supported by Sir E. Lechmere, Mr. J. Furley, Mr. V. B. Kennett, Captain R. Dallas, Captain H. C. Perrott, and other gentlemen. The chairman said the movement which they had met to further had scarcely any parallel in modern times. The assistance which had been rendered by the medical profession had been most marked; but they would never have done what they had if it had not been for the great enthusiasm and hard work in the first instance of Colonel Duncan and the perseverance and talent of Mr. Furley. Dr. H. Swete of Worcester then brought forward some suggestions for securing uniformity in the Association's examinations, and for improving the stretcher-drill. Surgeon-Major Evatt proposed that the nursing certificate should be thrown open for competition by the male classes. Dr. A. S. Eccles suggested, and Surgeon-Major Hutton seconded, measures for more efficient instruction in the treatment of the apparently drowned. Colonel Paris, chairman of the Liverpool Centre, then exhibited some interesting and useful models for illustrating the lectures. In the evening a dinner was held at the Holborn Restaurant, Sir E. Lechmere presiding. At a meeting of the Association on the 29th ult., a lecture was delivered by Baron Dr. Mundy on the urgent necessity for making Surgical Provision for Railway Accidents.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

DAVIES, JOHN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District of the Bath Union.

DIXON, J. R. L., M.R.C.S., L.R.C.P.Ed., has been appointed Junior House-Surgeon to the Royal Southern Hospital, Liverpool, vice A. H. Gordon, M.R.C.S., promoted.

FOX, ROBERT FORTESCUE, M.R.C.S., L.S.A.Lond., has been appointed Resident Physician to the Strathpeffer Spa.

GORDON, A. H., M.R.C.S., L.R.C.P.Ed., has been appointed Senior House-Surgeon to the Royal Southern Hospital, Liverpool, vice W. H. I. Sellers, M.B., C.M., resigned.

HENRY, ROBERT, M.D., M.Ch.Q.U.I., has been appointed Medical Officer of Health for the Comber Dispensary District.

HUDSON, CHARLES LEOPOLD, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Middlesex Hospital.

JOSEPH, J. RAPHAEL, L.F.P.S.Glas., has been appointed Resident Surgeon at the Hospital for Pacific Islanders in the Maryborough District, Queensland.

KNIGHT, F., M.B.Lond., M.R.C.S., has been appointed Second House-Surgeon to the Royal Southern Hospital, Liverpool, vice F. J. Allen, M.A., M.R.C.S., L.R.C.P., resigned.

LEDIARD, H. AMBROSE, M.D.Ed., F.R.C.S.Eng., has been appointed Surgeon to Her Majesty's Prison, Carlisle, vice J. A. Macdougall, resigned.

MACINDOE, ALEXANDER, M.B., C.M.Glas., has been appointed Medical Officer for the Ashley District of the Drayton Union.

MOFFITT, J. ERNEST JAMES, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Acting Resident Medical Officer to the Ballarat Hospital, Victoria.

PHILLIPS, EDWARD ENGLAND, L.R.C.P., M.R.C.S., & L.S.A.Lond., has been reappointed Medical Officer of Health for the Southend Urban Sanitary District.

PIGGOT, ALLEN, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fifth District of the Bromley Union, vice Booth, resigned.

SHEILD, MARMADUKE, M.B., B.S., F.R.C.S., has been appointed Curator of the Museum of St. George's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE. — On the 24th ult., at 56, Harley-street, Cavendish-square, W., the wife of Charles A. Ballance, M.S.Lond., F.R.C.S.Eng., of a daughter.

LEADAM.—On the 23rd ult., at Gloucester-terrace, Hyde-park-gardens, the wife of W. Ward Leadam, M.D., of a daughter.

RYAN.—On the 24th ult., at Emly, Tipperary, the wife of Charles E. Ryan, M.D., of a daughter.

MARRIAGES.

BROWNE—FLEMING.—On the 30th ult., at Glenorchy House, Edinburgh, by the Rev. Lewis Davidson, M.A., of Mayfield, F.C., assisted by the Rev. Dr. Reid, of Lothian-road U.P. Church, W. J. Browne, L.R.C.P.Ed., L.R.C.S.Ed., of 33, Warrender-park-road, Edinburgh, to Gracie Strang, elder daughter of the late Patrick Fleming, and granddaughter of the late Sir Robert Boag, J.P., of Belfast.

BROWNE—WILSON.—On the 23rd ult., at Christ Church, Highbury, Robert Browne, M.D., eldest son of the late Hugh Browne, Esq., J.P., of Rathgar, Dublin, to Frances, second daughter of the late John Wilson, Esq., of Compton-terrace, Highbury.

CUFF—SAWYER.—On the 24th ult., at St. Mary's, Lewisham, Robert Cuff, M.B., of Scarborough, to Marian, eldest daughter of John Sawyer, of Craythorne House, Lewisham-hill.

HARRIS—CURTIS.—On the 24th ult., at the Congregational Church, Wellingborough, U.A. Carpenter Harris, M.R.C.S., L.D.S.Eng., of Mount-view-road, Hornsey, London, eldest son of Underwood P. Harris, of Bethune-road, Amhurst-park, to Nellie, second daughter of Thomas S. Curtis, of Rose-hill, Wellingborough.

NICHOLSON — BEDWELL. — On the 29th ult., at All Saints' Church, Hull, Frank Nicholson, M.D.Lond., of 29, Albion-street, Hull, to Grace, second daughter of F. A. Bedwell, Esq., Judge of County Courts.

SCOTT—TRASK.—On the 29th ult., at St. Mary's Church, Bathwick, by the Rev. J. J. Scott (father of the bridegroom), assisted by the Rev. J. C. Clutterbuck, D.D., and the Rev. A. Cassan, Richard J. H. Scott, Esq., M.R.C.S.Eng., to Alice Marian, eldest daughter of James Trask, Esq., of Bayfield House, Bathwick-hill, Bath.

STATHERS — ABBOTTS. — On the 29th ult., at Holy Trinity Church, Burton-on-Trent, by the Rev. W. F. Drury, George Nicholson Stathers, M.R.C.S., of Stokenchurch, Oxon., to Maud, second daughter of R. W. Abbotts, Esq., of Burton-on-Trent.

DEATHS.

BELL. — On the 28th ult., at Manor-place, Edinburgh, Alexander Montgomerie Bell, M.D., F.R.C.S.E.

RIORDAN.—On the 10th ult., at Marksbury, Somerset, Thomas Travers Riordan, M.D., formerly of Castleconnell, co. Limerick, aged 80.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

WESTERN AS A HEALTH RESORT.

WE are glad to learn from a correspondent that the drains have been thoroughly overhauled and put in order, as promised; and that the system of drainage and the watercloseting are better, in his own experience of the past three winters, than at any place on the Riviera or Engadine.

Mr. John Fletcher Little.—We do not know of any decided cases, but we are clearly of opinion that "any aged person who cannot write" can make a sound will. All that is legally necessary is that the testator shall at the time understand the nature of the act, and be able to sign the deed—it may be with the physical aid of another person. As, however, such a will might not improbably be disputed, it would be well for it to be accompanied by a certificate signed by two competent independent medical witnesses. By "competent" we mean, well versed in the forms of interference with the outward expression of thought and other mental operations, and the bearing these have upon the rationality of a particular process—*e.g.*, making a will.

Quimdarly dent ethers.—We may probably in a future number give some general information on the point.

VACCINATION WITH OLD LYMPH.

To the Editor of THE LANCET.

SIR,—The success attending Dr. N. Gosset-Brown in his use of fourteen-year-old lymph, as communicated by him in your issue of July 19th, cannot fail to be interesting; and I feel sure that your readers will be glad to receive further citations as to success or non-success following the use of old lymph, with a view of really ascertaining as to what length of time vaccine lymph may be supposed to retain its virtues and properties, as there is very little (if any) authentic information given on the subject.

A short time ago I had the opportunity of testing the efficacy of some lymph collected so far back as February, 1864, by the late Mr. Robert Ceely of Aylesbury. The contents of six hermetically sealed tubes were tried on six individuals, members of different families, and all of whom have since been successfully revaccinated with recent lymph, with the result that in every case the lymph proved itself perfectly inert. I may say that, contrary to my expectation, the lymph was in a fluid state and had apparently lost much of its specific gravity, for it was (for vaccine lymph) particularly thin and watery. I regret that I did not carefully examine it microscopically, and that I do not possess any more.

I am, Sir, yours obediently,

Regency-street, S.W., July 22nd, 1884. CHARLES F. RIDEAL.

THE FORTHCOMING MEDICAL AND PHARMACEUTICAL EXHIBITION.

WITH respect to the contradictory statements which have appeared in the daily journals regarding the use of the names of the medical staff of University College Hospital in support of a Medical and Pharmaceutical Association, Mr. Berkeley Hill, Dean of the Faculty of Medicine and Chairman of the Medical Committee of University College Hospital, states: 1. That the secretary to the Hospital, Mr. Nixon, greatly exceeded his instructions by stating that he (Mr. Hill) had agreed to the use of the names of the medical staff of the hospital when he wrote, on June 19th, to Mr. Southwick Rogers the letter which that gentleman has published with his own of July 23th in the daily newspapers. 2. That when the medical committee of the hospital met on July 9th, the application for the use of the names of the medical staff was considered, and positively refused by that body. Reference to the hospital letter-book shows that on July 11th Mr. Nixon wrote to Mr. Rogers two letters enclosed in one cover, one informing him that the medical staff declined to give the use of their names, the other concerning some other matter. On July 12th Mr. Humphreys, through his clerk, acknowledged the receipt of Mr. Nixon's letter of the 11th, and said it had been forwarded to Mr. Southwick Rogers. 3. That the circular containing the names of the medical staff, in spite of this prohibition, came first under his notice on July 26th, when he wrote to the daily newspapers a warning that the names of his colleagues were being used without their consent. He wrote at the same time to Mr. Southwick Rogers, requesting that he would at once withdraw the circular from circulation, and informing him of what had been done with regard to the public newspapers.

A. H.—Absolute cleanliness and avoidance of perturbation as far as possible are the only general precautions that can be indicated. Contraction of disease by nurses fitted to their work is very unusual.

Major Terry is thanked for his communication.

INFANTILE DISEASE AND MORTALITY.

To the Editor of THE LANCET.

SIR,—During my short residence here I have been struck by the number of patients brought up for treatment suffering from the effects of improper feeding, and by the number of cases which inevitably succumb, notwithstanding the advice and medicine given, in consequence of prolonged malnutrition. I refer to two classes of cases: first, those patients, young babies under nine months, who are fed with all kinds of patent farinaceous foods, biscuits, arrowroot, bread, and the like; and, secondly, children varying from eighteen months to two and three years, who are fed with very little else besides the impoverished milk from their mothers' breasts. It has occurred to me that possibly some good might be effected were every institution of this kind to hand all the out-patient papers or cards with the instructions that "no child should under any circumstances be fed with anything but milk from the breast or cow's milk and water until nine months old," and that "continued suckling after this time is bad both for the baby and its mother." Some such instructions would, at all events, embrace the rough truth, and if followed out would prevent much of the deplorable sickness we see every day, and the loss of life which is of such common occurrence.

I am, Sir, yours truly,

HARDING H. TOMKINS, M.R.C.S.,
Assistant House-Surgeon, Infirmary for Children, Liverpool.

July 28th, 1884.

Veritas.—We think that an assistant should consult with his principal both as regards any serious case and the propriety of giving it up.

Enquirens shall be answered next week.

PYRETHRUM ROSEUM AS A DISINFECTANT.

PROFESSOR C. V. RILEY, the well-known American entomologist, has presented to the Committee of the International Forestry Exhibition in Edinburgh a series of reports on the best mode of preventing the damage done by insects to trees. He is strongly of opinion that for the destruction of the micro-germs to which so much epidemic disease has recently been traced effective use might be made of the pyrethrum roseum of Asia, which, he says, has lately been imported into America, and is cultivated in large quantities for the sake of its flowers, which contain a volatile oil of great value as a field insecticide. As to kerosene as a disinfectant, he has found the subjoined formula particularly efficacious:—Kerosene, two gallons; common soap, half a pound; water, one gallon. The mixture of soap and water is added boiling hot to the kerosene, and the whole is then churned with a force-pump for five or ten minutes, forming a cream, which thickens on cooling, and adheres without oiliness to the surface of the glass. From this formula three gallons of emulsion are obtained, which, with water, may be made into three gallons of wash, the cost being about three farthings a gallon. In applying it a force-pump and hose with a nozzle (newly invented by Professor Riley) are used, the new nozzle being capable of producing the finest atomised spray.

HISTORIC DROUGHTS.

AN Italian *savant* passes in review the hot years of history, beginning with 68 A.D., in which the water-supply of France, Germany, and Italy was completely dried up. In the year 897 the heat was so great on the Continent that vast numbers of peasants were struck down with *coup de soleil* in the fields; in the year 993 vegetation was burnt up by the sun as if by fire; in A.D. 1000 the wells and watercourses were all dried up, and the masses of fish heaped up on the banks of rivers and lakes produced a pestilence by their putrefaction. In 1132 the earth was so scorched with the intense solar heat that great fissures were made in it for miles, and seven years afterwards the same phenomenon was witnessed, especially in Italy. The years 1260, 1277, 1303, and 1304 were all signalised by protracted drought, insomuch that the largest rivers in Europe, the Rhine, the Seine, the Po, the Tiber, shrunk to the tiniest streamlets. In 1615 and 1625 a similarly excessive heat prevailed all over Europe, and in 1705 the temperature rose so high as sometimes to resemble that of a glass manufactory. Butcher's meat was cooked by the sun, and from mid-day till 4 P.M. no one ventured out of doors. For six months in 1718 not a drop of rainwater fell, and in 1753 the thermometer averaged between 88° and 40° C. Bologna was visited by excessive heat in 1779, so that many died of asphyxia, and to escape a similar fate the inhabitants took refuge in pits and caves underground. The month of July, 1793, was also one of intolerable heat. All the vegetation and the harvest withered up. The furniture in houses cracked and split, and meat became putrid almost under the butcher's hands. Hurricanes and earthquakes accompanied the intense droughts of 1811 and 1822. In some countries the earth delivered itself, under the contained heat, of hosts of field mice, which ravaged the most fertile plains. Of these mice no fewer than 2,000,000 were destroyed in fifteen days in one country alone. In 1832 the fearfully hot weather in Paris was coincident with the cholera epidemic in which 20,000 persons died.

Mr. Alex. Faulkner.—The point mentioned is hardly of sufficient importance for publication.

Mr. Thomas Jones.—We do not recommend practitioners.

SANITARY STATE OF HYERES.

To the Editor of THE LANCET.

SIR,—My attention has been directed to a communication from a correspondent in THE LANCET of July 19th, entitled "Cholera and Sanitation on the Riviera." In justice to Hyères and its enterprising and liberal-minded municipal council, will you allow me to suggest that, however true the striking picture drawn by your correspondent may have been years ago, it is no longer so. Old streets have been widened and purified, new streets have been made, and all the water channels have been cleaned out, properly levelled, and are regularly flushed. There are no sewers as understood in England. These channels exist only for surface water; everything else is cast into the cesspools, except the kitchen refuse, which is placed in the street during the night, and carted off before daybreak. The cesspools are carefully superintended and regularly emptied; in the villas and hotels occupied by English visitors they are efficiently ventilated, and the waterclosets trapped. The municipality are making every effort to ensure that Hyères shall be a health resort in more than name; that the benefits conferred by its mild, stimulating climate shall not be marred by preventable evils; and from my own experience—an experience extending over seven years—I can vouch for the success of their endeavours.

I am, Sir, yours truly,

W. P. BIDEN, L.R.C.P.Ed.

St. Mary's-road, Peckham, S.E., July 28th, 1884.

TREATMENT OF LUPUS VULGARIS BY THE THERMO-CAUTERY.

A paper of an article in THE LANCET of the 26th ult. on the "Complete Destruction of Lupus Vulgaris," with illustrations of an instrument, Mr. [illegible] reports a case which recently came under his notice in the [illegible] and Galloway Royal Infirmary, in which the disease lupus [illegible] extended over the greater part of the left cheek and side of [illegible] involving the ear, half of which was eaten away; it also [illegible] down the front of the neck, over and under the chin, and [illegible] cheek nearly to the right ear. To scarify or scrape so [illegible] was thought rather a serious undertaking; but something [illegible] be done. On the morning of the operation the use of a [illegible] cautery was decided upon. When the patient, a lad nineteen years of age, was fully under chloroform the gelatinous covering of [illegible] was rubbed off with a hard sponge and pledgets of cotton-wool, and the thermo-cautery applied to the denuded and bleeding surface. This was done [illegible] as to avoid excessive [illegible]. The sore was dressed with weak boracic ointment, and a [illegible] injection of morphia given for the pain. This treatment turned out most successful. The raw surface showed healthy granulations from the first, and, except an occasional touch of the cautery to some sluggish spots, the case required no further treatment, the skin healing nicely, to the satisfaction of all concerned.

A MEDICAL PATRON IN THE ISLE OF MAN.

A MOST astonishing account reaches us of the action of a distinguished official in the Isle of Man. Not content with appointing a complete stranger, a young medical man, to an official professional position over the heads of three or four senior medical residents, he has given his *protégé* a letter of introduction to the manager of the principal hotel. The fortunate young man seems only too much of a consenting party to this strange and unusual action of his patron. We suppress names at present, as really the account seems almost incredible, either as regards a high official or a recently qualified, and doubtless modest and diffident, member of the profession.

Medical Student.—We do not doubt that anyone who is familiar with the ophthalmoscope would be able to recognise coarse disease of the fundus of the eye—such, for example, as the presence of blood clots, detachment of the retina, and even optic neuritis, if well marked; but we should expect that in a case which was about to become the subject of medico-legal inquiry the ophthalmoscopic examination would be conducted with all the precautions requisite to avoid error, amongst which a darkened chamber and a good steady light are conspicuous.

Dr. Theodore Euart.—The paper is marked for insertion.

SMALL-POX *ALIAS* CHICKEN-POX, &c., IN BASUTOLAND.

To the Editor of THE LANCET.

SIR,—A leading article in your issue of May 10th on the unfortunate discrepancy of opinion amongst the members of our profession at Kimberley and elsewhere as to the real nature of the epidemic of eruptive fever now raging amongst the native population in some parts of South Africa leads me to believe that an account of this disease as seen by me in Basutoland may be interesting.

The disease has in many cases all the premonitory symptoms of ordinary small-pox, the head symptoms being the first complained of, and almost always present, though the lumbar pains and vomiting are absent. The eruption, as regards incubation, development, and decay, corresponds very nearly in essential particulars with that seen in small-pox. The vesicles, however, are not of one uniform shape; some are oval, some are round and umbilicated. The oval ones collapse on being pricked, the round ones do not. Those vesicles appearing in the mucous membranes of the mouth are always of the round umbilicated form, and should, in my opinion, decide the true nature of the disease. When the principal proportion of the vesicles are small oval-like blisters, and collapse on being pricked, one might be led to say that the case resembled more closely chicken-pox than small-pox; possibly others may have been misled on similar grounds. In the discrete the vesicles frequently commence to die or dry up as they appear, but generally the case proceeds from its commencement to its termination in the usual manner. The confluent generally die from the tenth to the fifteenth day of the eruption. Delirium is not a marked symptom, and these cases have not given very much trouble. There is not much pitting or much smell from the confluent cases. The form most frequently met with is the confluent. The persons attacked are of all ages; the old and young are the first victims, the old, as a rule, dying first. Many die in the eruption begins, others at the suppurating stage, and but few between these stages. Where isolation has been carried out and quarantine kept the disease has not spread. No European has been attacked yet, and only three coloured people, one of whom died of confluent small-pox. Most of the coloured population have been vaccinated, and the three cases referred to are the only exceptions, for not one of them was vaccinated.

I am, Sir, yours truly,

Basutoland, June 15th, 1884. S. CARNEGIE REID, M.D.

Mr. E. T. Le Quesne.—By no means.

Mr. Roderick Maclaren.—The suggestion shall receive consideration.

THE HEALTH EXHIBITION.

A CORRESPONDENT suggests the opening of the Health Exhibition on Sundays free of charge, visitors to be invited to contribute to the Hospital Sunday Fund, boxes being placed for that purpose in different parts of the building.

Balbus.—Probably Niemeyer's work would answer the purpose.

Dr. G. Ogilvie.—Yes.

Dr. Barrs (Leeds).—In an early number.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir Lyon Playfair, London; Dr. Goodwin Timms, London; Dr. Maclaren, Carlisle; Dr. Byers, Belfast; Dr. Kerr, Dumfries; Dr. Sturges, London; Mr. Jones, Manchester; Mr. J. Clinical Remarks ON GASTROSTOMY; WITH CASES.

By THOMAS JONES, F.R.C.S.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

GASTROSTOMY, formerly so uniformly unsuccessful, promises to become a palliative measure of decided utility. To Sédillot, of Strasburg, belongs the credit of introducing both the operation and the name. In 1849 he performed gastrostomy on a male patient fifty-two years of age, who was the subject of cancerous stricture of the œsophagus. The stomach was opened at once, and the aperture in it fitted with a tube, which embraced an elastic catheter, introduced for the purpose of conveying nourishment. Unfortunately the attempt proved unsuccessful, as also did a repetiton of it during many succeeding years. The record of the cases operated upon between 1849 and 1876 constitutes an unbroken series of failures. The operation was repeated some twenty-five times, and most of the patients died within the first few days; some of them lived periods varying from four to ten days, and one survived forty days. In 1876, Verneuil, of Paris, obtained the first real success. His patient, a healthy lad, seventeen years of age, some months previously had swallowed a solution of caustic potash. This was followed by intense pain in the throat, with exfoliation of the mucous membrane of the stomach. When the acute symptoms subsided the patient experienced great difficulty in swallowing. The dysphagia increased, and attempts at catheterism of the gullet were frequently made, but without success. The stricture was situated about seven inches below the upper end of the gullet, and so low as to preclude the idea of œsophagostomy; it was therefore decided to perform gastrostomy. The portion of stomach exposed was carefully stitched to the lips of the wound in the peritoneum and abdominal wall. The viscus was then laid open and a vulcanite tube introduced. The patient made a good recovery, and almost at once was able to take liquid food through the artificial opening. At the time of operation the weight of the patient was 72 lb., a month later 75 lb., and three months later 92 lb. The lad lived seventeen months.

I have referred somewhat at length to this case because it forms the commencement of an important era, and constitutes the first of a limited number of successful gastrostomies. Since 1876 the operation has been frequently repeated. The most elaborate statistics of the results are those published by Blum.[1] He tabulates 131 gastrostomies, of these eighty-five died before the twentieth day—that is, in consequence of the operation, and so giving a mortality of nearly 65 per cent. Thirty-eight have survived the operation from several months to two years and more. One other point which these statistical tables bring out is worthy of our attention. By eliminating the gastrostomies for cancerous disease of the œsophagus we have left twenty-five examples in which the operation has been performed for fibrous or non-cancerous strictures. Of these only twelve patients died before the twentieth day, showing a mortality of 48 per cent. I think that if the merits of gastrostomy had no other basis than its success in non-cancerous strictures, it ought to claim our respectful consideration, and it is quite possible that if in cancerous cases we resorted to the operation at an earlier period and before the patient's powers had fallen to a low ebb, the successes would be more numerous. What particularly attracted my attention while perusing reports of gastrostomy cases was the rapid sinking soon after the operation. The little remaining strength has been quite unequal to the task of rallying. Even in these cases by an improvement in the mode of operating the chances of a successful issue are very materially increased. In THE LANCET of January 7th, 1882, I published a successful gastrostomy for non-cancerous stricture of the œsophagus. The patient (a female, now aged twenty-two) is still alive, and is able to work in a cotton mill, while she continues to introduce fluid food through the artificial opening. Quite lately, through the kindness of my friend Mr. Waller, late house-surgeon to the Blackburn Infirmary, I have been able to obtain an accurate statement of her condition. He writes to say that he has visited Mary N——, and found her in a very satisfactory condition. The general nutrition is good, and saliva and fluids can be swallowed with ease. The gastric aperture is patent, and is kept so by the patient constantly wearing a small plug, which accurately fits the artificial opening. A short time ago there was some slight eczema around the opening, which has now disappeared. The patient's weight was found to be 101 lb, which is considerably more than when she was last seen at the infirmary. This case must be regarded as one of the most satisfactory gastrostomies. Here was a patient doomed to one of the most distressing deaths—that from inanition—restored to a condition of comparative comfort; and it is quite possible deglutition may continue to improve, and that eventually dilatation of the stricture may be accomplished.

CASE 2.—Ann W——, aged forty-five, was admitted under Dr. Dreschfeld's care on June 21st, 1882. She was found to be suffering from stricture (malignant) of the œsophagus. There was no history of syphilis, and no corrosive fluid had been swallowed. Present disease commenced seven months before admission, with vomiting immediately after taking food. She soon began to lose flesh and to experience shooting pains down the inner side of the left arm. The vomiting was not accompanied by any exertion, but simply consisted of the regurgitation of unaltered food. An œsophageal bougie passed readily a distance of thirteen inches, when its progress was suddenly arrested. While under treatment emaciation steadily advanced, although she was fed by nutrient enemata. On July 3rd the patient was transferred to a surgical ward under my care, with the view of gastrostomy being performed. No difficulty was experienced during the performance of the first part of the operation, which was done on July 4th. The stomach was easily reached by making an incision below the left costal margin, commencing above opposite the anterior extremity of the seventh intercostal space. Care was taken that all oozing had entirely stopped before the peritoneum was incised. The stomach presented at the opening, and its peritoneal and muscular coats were stitched to the margins of the skin incision. The parietal peritoneum was not included. The number of sutures (chromised catgut) employed did not exceed half a dozen, and I feel convinced that the unfortunate termination of the case must to a certain extent be attributed to this cause. For six days afterwards no special symptoms appeared. The temperature continued about the normal, and there was an absence of pain. During this time the patient was exclusively fed on enemata, which consisted of three ounces of beef-tea or milk (peptonised) and four drachms of whisky every two hours. On July 10th the antiseptic dressings were removed, and the wound appeared healthy. The stomach was now opened with a tenotomy knife, a catheter introduced, and a small quantity of warm milk injected. The next day a pint of milk was administered by the artificial aperture, while the nutrient injections were continued. The patient progressed favourably until the 16th, when through an unlucky mishap a pint of cold milk was poured into the stomach. Immediately she became collapsed, and was seized with a rigor; afterwards the temperature rose to 102°, delirium, followed by insensibility, supervened, and the patient died in about fifteen hours. A short abstract of the post-mortem examination is appended. The body was well developed, but greatly emaciated. The margins of the gastrostomy incisions were united to the walls of the stomach, except at one part, where no adhesion had taken place. The tissues in the region of the incision were more or less infiltrated with purulent matter, and the underlying peritoneum acutely inflamed. The peritoneum was coated with a thin layer of inflammatory exudation. This was most marked (excluding the vicinity of the wound) in the region of the ovaries, both of which were intensely congested. The œsophagus was normal down to three inches and a half from the cardiac end, where the lumen was almost obliterated by a dense whitish mass of new formation (cancerous), which involved the whole circumference of the tube, and extended downwards about an inch and a half. To all appearance the fatal termination was immediately due to the accidental administration of milk which had not been properly warmed. The post-mortem, however, revealed an amount of peritonitis which in all probability had been going on insidiously for some days,

[1] Archives Générales de Médecine, November, 1883.

Digitized by Google

although the temperature and general symptoms contra-indicated such an assumption. The case clearly shows that great care is absolutely needed in carrying out the after-treatment. The milk or other fluid food poured into the stomach through an artificial opening should have a temperature of not less than 100°.

CASE 3.—Sarah A——, widow, aged fifty, was admitted into the infirmary under Dr. Leech's care in August, 1883. She was an in-patient for a week in March of the present year; was then sent to Cheadle Convalescent Hospital, where she remained six weeks, and appeared to derive considerable benefit. Her symptoms at that time were chiefly those of dyspepsia, with attacks of vomiting every three or four weeks. The vomited matter consisted of a dark brown fluid, which bore some resemblance to coffee grounds. Pain of an aching character, referable to the region of the stomach, accompanied each act of vomiting. No family predisposition to cancer could be discovered, and inquiry into a history of syphilis only gave negative results. Patient had never swallowed any corrosive fluid. The passage of an œsophageal bougie determined the presence of a stricture which was impassable and situated about fifteen inches and a half from the mouth. On August 16th, 1883, she was transferred to the surgical side of the infirmary. At that time she was very haggard, and had an exhausted anæmic appearance. For some days she had been fed on peptonised beef-tea and milk administered by the rectum. The injections were continued, and her weight increased from 90 lb. to 95 lb. Any fluid food given by the mouth appeared to stop before it reached the stomach, and in a few minutes was regurgitated. On Sept. 20th the first part of the operation of gastrostomy was performed with antiseptic precautions. No difficulty of any kind was met with, and the stomach was easily drawn forwards and sutured to the skin. In order to accurately approximate the peritoneal and cutaneous surfaces the number of sutures employed was about a dozen. After the operation all food by the mouth was stopped, and the patient fed by enemata of beef jelly and milk (an ounce of each) every two hours. The temperature for the most part maintained a normal course, reaching 99° on the 22nd. There was freedom from pain or any symptom of peritonitis. Fortunately the enemata were well retained. On the 26th the dressings were removed for the first time; the parts appeared healthy, and adhesions had taken place between the opposed surfaces. I now proceeded to make an opening into the stomach by means of a tenotomy knife. Through the opening a cannula was passed, and about a third of a pint of milk injected. This caused a stomach-ache, and during the night the patient became collapsed, and complained of pain in the abdomen. The cannula was withdrawn, and all attempts at the introduction of milk postponed until Oct. 4th—i.e., for eight days. Meanwhile the local and general symptoms indicated an attack of circumscribed peritonitis. For a week the temperature continued at or about 100°, and one evening it exceeded 101°. The fever had subsided by Oct. 4th, when a more successful attempt to open the stomach was made. A cannula was again inserted through a puncture produced by the tenotomy knife and six ounces of milk introduced. The cannula was retained *in situ* until the next day, when sixteen ounces of milk were poured into the stomach without causing any pain or inconvenience. The nutrient enemata were discontinued on Oct. 10th, and four pints of milk were administered daily through the artificial opening. About a month after the date of the first operation she was weighed, and found to be 87 lb., which is 9 lb. less than her weight immediately before operation. Six weeks later the weight was again taken and an increase of 13 lb. recorded. Each time the patient has been seen since her discharge a considerable increase in the weight has been noted. The patient is now in the enjoyment of very good health. The artificial opening occasions no inconvenience, nor does the surrounding integument bear any evidence of regurgitation. She is quite satisfied with the fluid food, and its introduction causes no sensation, except that of heat or cold. The condition of the stricture remains practically the same, and any food which is swallowed is instantly rejected.

CASE 4.—Ann B——, aged thirty-nine years, admitted under Dr. Leech's care, on Oct. 12th, 1883. She is emaciated to an extraordinary degree, and, although of ordinary stature, she only weighs four and a half stones. The history of dysphagia extended back a year and ten months, and has been accompanied by symptoms of dyspepsia. At first the sickness recurred at intervals of a fortnight, but lately it has taken place immediately after each meal. She says she feels the milk pass down a certain distance, where it remains a few minutes and is then regurgitated. The patient has never swallowed any corrosive fluid, and no history of syphilis or cancer can be elicited. An œsophageal bougie can be easily passed a distance of twelve inches from the mouth. Its further progress is then suddenly and completely arrested. Three days after admission she was transferred to the surgical ward. For some time an attempt, partially successful, to improve her condition was made. By the aid of nutrient enemata her weight was increased by four pounds. On Nov. 3rd the first part of the operation was performed. No difficulty was experienced, the stomach being easily reached and brought forward. During the following week the patient was in an exceedingly low condition, and fears were entertained that it would be quite impossible to preserve life until the stomach opening could safely be made. However, by the careful administration of enemata and the free use of stimulants I succeeded in carrying her through a very anxious period. The operation was completed on Nov. 10th, and ten ounces of milk were at once introduced through the newly made opening without producing any pain or uneasiness. In a few days the quantity of milk administered by the artificial aperture was increased to five points, so the nutrient injections were discontinued. For some time she was much troubled by the regurgitation of a dark, grumous, exceedingly offensive fluid, which was brought up whenever she had a fit of coughing. No doubt it came from the œsophagus, which, in all probability, was dilated above the stricture. Its gastric origin was excluded by the non-appearance of the milk in the regurgitated fluid when the stomach was opened. The quantity of fluid gradually diminished, and finally ceased. Very soon she began to improve in appearance and to put on flesh, and we were able to register an increase of 8 lb. in her weight. Since her return home she has been heard of from time to time. At first there was a steady and continuous improvement, and she added considerably to her weight. Unfortunately, however, the amendment has been arrested by an attack of pneumonia, from which she is slowly convalescing.

CASES 5 and 6 terminated fatally about thirty hours after operation. Both were males. One patient, seventy years of age, had suffered dysphagia for thirteen months. From the distance the bougie traversed it was judged that there existed a stricture at the lower extremity of the œsophagus. No difficulty attended the operation. The patient rallied well, and remained free from pain for more than twenty-four hours, when the symptoms suddenly declared the onset of peritonitis. The temperature rapidly rose, and death took place in a few hours. In the other patient, a man forty-seven years of age, the sequence of events was practically the same. Death followed the operation after a similar interval, and was preceded by symptoms of a like nature. As no post-mortem examination was made in either case, the exact state of things must remain a matter of conjecture.

It should be noted that the method of operating in all the foregoing cases was that introduced by Mr. Howse. It constitutes an undoubted improvement over the plan formerly in vogue. By delaying the second stage of the operation for some days we obtain adhesions between the peritoneal covering of the stomach and the margins of the skin incision, so that when the stomach opening is made extravasation of the gastric contents into the peritoneal cavity is effectually prevented. French surgeons seek the same end by a double row of sutures, the first row between the parietal peritoneum and the serous covering of the stomach, and the second between the skin and the gastric opening. Mr. Howse's plan is preferable, and for several reasons. It not only removes all chances of extravasation into the peritoneal cavity, but it permits the first and most important part of the operation to be conducted with antiseptic precautions. Everyone who has practised gastrostomy will have been struck with the simplicity of the operation. As a rule, the stomach is found without any trouble being experienced. The late Mr. Maunder, however, encountered a serious difficulty which caused him to open the transeverse colon instead of the stomach. To avoid a similar accident Schönborn has suggested that a small india-rubber bag should be fixed to the end of an œsophageal tube. As soon as the latter reaches the stomach the bag is distended. This brings the anterior wall of the stomach into the wound and the operation is clearly rendered easier. Of course this suggestion presupposes the permeability of the

Digitized by Google

stricture, which is rarely the case, and when present would perhaps contra-indicate an operation. An attempt has been made to institute a comparison between œsophagostomy and gastrostomy. It would appear that they are applicable to different cases. Œsophagostomy may be appropriately employed in those cases where the obstruction is seated in the upper part of the gullet. Experience, however, teaches that these constitute the smallest class. It has been found that in nearly two-thirds of the cases of œsophageal cancer the disease is so situated as to render œsophagostomy inadmissible.

Some discussion has taken place in regard to the position which the gastric aperture should occupy. Langer,[3] arguing from physiological data, concludes that the fistula should be established in the cardiac portion, and not, as is frequently done, in the pyloric part of the organ. No doubt surgeons have made the opening in that portion of the viscus which presents, and I think it will be found that this is generally nearer the pyloric than cardiac extremity.

THE UNIVERSALITY OF CHOLERA.

BY DEPUTY SURG.-GEN. W. T. MOORE, C.I.E.

CHOLERA may be defined as a disease always present and frequently becoming epidemic, generally characterised by purging and vomiting, usually of a material resembling rice-water, commonly accompanied by cramps, and frequently resulting in suppression of urine and collapse. But the term cholera implies a principle which is repugnant to the disease; the term cholera signifies a flow of bile, but the want of bile is usually one of the most prominent peculiarities of the complaint. It is impossible, therefore, to use the term cholera without pointing out the absurdity of an expression which literally implies, not what it ordinarily is, but what it ordinarily is not. And this should be borne in mind, as tending in some degree to account for the numerous names under which cholera has been described, as a consequence of the numerous phases in which it develops itself. Allen Webb[2] long since remarked that much of the mystery and obscurity which attaches to cholera results from its having been regarded—since 1832 in Europe and since 1817 in India—as an entirely new and previously unheard-of malady; and he shows, by quotations from Snohruta, Wangohoo, and other ancient authors, that cholera is as old as India or China. "It is not always the same in its nature or effects. It is allied in its nature to some of the most desolating pestilences, as well as to some of the most common diseases." In its virulent form it begins, as Magendie observed, "in death." On the other hand, as with all other diseases, there may be a most mild and scarcely recognisable form of the malady. Of all writers, Macpherson[4] has, I think, most elaborately and satisfactorily shown that cholera is one of the most ancient diseases of which distinct descriptions exist, prevailing both in Europe and Asia from the earliest times. In support of the view of cholera having prevailed in early times in Europe, Macpherson refers to Hippocrates and Galen, who described a malady very similar to modern cholera; and he further demonstrates that cholera in one or other of its diverse forms has been described by successive European authors almost from the time of the ancients mentioned to the present date, and especially during the 14th, 15th, 16th, and 17th centuries. That cholera has been looked upon as a new disease in Europe since 1832 may be explained by the facts that medical writings of a reliable nature referring to former times were few, and that many of the writings extant, in consequence of the extraordinary variations which occur in the manifestations of the disease itself, do not describe that typical cholera which occurred in 1832, and which has come to be accepted as the only phase of the malady. Even analogous reasoning would teach that cholera prevailed in Europe and England in former times; for, as Surgeon-Major Waters[5] points out, considering that cholera is endemic only in countries where fevers of a malarious character are invariably to be found, and that these were common in England till a comparatively recent period—James I. and Cromwell having died of ague,—it may be inferred that when the latter prevailed in full virulent vigour, the former occurred in epidemic periodicity, as it does in India.

In support of the view of the antiquity of the malady in the East, there is the fact that the early Sanskrit writers were apparently well acquainted with cholera. In the Midan of Snohruta there is a description of a disease termed "vishuchuka" (meaning purging, vomiting, and fever), which was clearly cholera; while in other old Hindu medical works we have "jivat antiahat," meaning fever and incessant purging. Then there is the significant fact that all the languages of the peninsula of India have a time-honoured name for the disease. Further, it appears to have been well known to the Mahomedan conquerors as "haidse" or "haiza," and it has been shown that cholera prevailed among the Mahomedans of Delhi in 1326. There is also a record in Todd's "Rajasthan," that temples to "Oola Bebee," the goddess of cholera, were found by the first European visitors in India. Macpherson makes the pertinent observation that as it is certain the Portuguese found cholera in India soon after their arrival in 1509, especially at Goa in 1540, it is only reasonable to believe that it existed in India previously. Mr. Gaskoin translated from the Portuguese a distinct notice of the disease occurring in 1503, when, as testified by Gasper Corea, 20,000 men belonging to the army of Zamoryn, King of Calicut, died, "sudden-like with pain in the belly." But the first full account given by a European physician was by Garcia D'Orta, of Goa, who, in 1653, pointed out several varieties of cholera, much as they exist now. The ideas, therefore, which have been held by many, and as stated below, cannot be regarded as tenable—viz., that Bontius in 1630 was the first writer on cholera; that cholera is a comparatively recent disease; and that, as concluded by the Constantinople Cholera Congress of 1854, some change came into operation about the year 1817, giving rise to the first great Indian cholera epidemic.

Even assuming, as Bryden held, that Bontius in 1630 first described cholera, I have before me references to no less than fifteen distinct notices of the disease from that period to 1784. Dr. Waters, indeed, states there are no less than sixty separate and independent testimonies to the occurrence of cholera in India during the 16th and 17th centuries. Lastly, there is no doubt it was recognised in the Madras Medical Board's reports previous to 1817. The fact is, our knowledge of the diffusion of cholera in India in earlier times is imperfect and limited, as our knowledge of the country was then imperfect and limited; but that it did prevail previous to 1817 appears indisputable, although perhaps called by other names. For instance, the word *modesh*, derived from *modwa*, to tear, was adopted by the Portuguese, corrupted into *mort de chien*, and often applied indiscriminately to the different forms of cholera.

It is true that some of the writings on which reliance is placed both in Europe and India, to prove the antiquity of the disease, do not always describe the malady marked by suppression of urine, rice-water stools, and collapse, which in the present day is held to be true cholera. But this is only in accordance with the very numerous variations of the malady, as is sufficiently demonstrated by the number of names under which it has been described even in modern times, each term originating in some peculiar phase of the epidemic recorded. Thus we have in the writings of European authors the terms—Cholera Asiatica, asphyxia, algide, bilious, black, blue, dry, epidemic, endemic, febris, remittens, choleroidea, cholera foudroyante, malarious, malignant, nervous, nostras, pestiferous, hæmorrhagica, serous, simplex, spasmodic, sporadic, syncopal, and tetanic. There is also cholerine, choleriform, choleroid disease, choleroid fever or sweating sickness, and the choleroid cholic of the Himalayas, which Webb regarded as a connecting link between cholera and colic. There is also reason to believe that cholera has been described as "white dysentery" and as *fièvre pernicieuse*. Now all these are comparatively recent terms called into use by the varying nature of the malady. The disease appeared under different phases, and both in India and in Europe was described as it appeared, and therefore under a different appellation. There is indeed no disease in which the symptoms, although retaining certain characteristics, vary more. This variability of the affection was noticed on the first reputed invasion of cholera into Europe in 1832, when Dr. Pennick[6] pointed out how the epidemic in England differed from the disease in Russia. Allen Webb asked, in India, about

the same time, "Who can tell where cholera ends and plague begins, or distinguish between certain forms of fever and cholera?" Macpherson states that the disease is essentially the same, but the cholera of one season varies from that of another. Ziemssen says that almost every epidemic has its physiognomy. Sir Guyer Hunter writes: "As there are varying degrees of fever, so there are varying degrees of cholera. It may manifest itself as a slight looseness of the bowels, or as a sudden paralysis of the vaso-motor system."[7] Chevers states: "Familiar as I am with the cholera of Calcutta, the disease I treated during a greater part of 1874 was of a type altogether new to me; no two cases of the disease were precisely the same." And, again: "As the malarious poison produces all variations, from a fatal remittent to the mildest ague, so with the cholera poison."[8] And such is the experience of most of those who have had much to do with cholera. In Bombay in 1883 persons died suddenly from collapse, without vomiting or purging, or after one or two loose stools. In other epidemics all the symptoms of cholera have occurred except that the stools were tinged with blood, mixed with blood, or even dysenteric. Often the premonitory diarrhœa is absent, and sometimes there are no cramps. At other times there are cramps and no purging. Sometimes the stools are not like rice-water, but colourless like serum. The similarity of cholera to fever is sometimes so great that both diseases have been attributed to the same cause—malaria. Cholera in its commencement may simulate an attack of ague, or terminate as fever. This is especially the case with the cholera of Peshawur. Cholera may also be so mild that the symptoms are scarcely recognisable. In every epidemic of cholera a large number of persons suffer from diarrhœa, which is, indeed, cholera in its mildest form. All this, however, is merely in accordance with other zymotic diseases, none of which are distinguishable by constant and invariable characters. As Carpenter has observed: "The peculiar morbific type of disease germ may be derived from the operation of particular environments on ordinary saprophytes through a long succession of generations." Mere degree is not sufficient ground for considering a disease different in essential character. There are mild and severe degrees of catarrh, influenza, scarlet fever, diphtheria, typhoid, &c.; some so mild as to be scarcely recognisable; and the symptoms of such diseases are sufficiently variable to often render diagnosis uncertain. But it has become the custom to regard cholera as a disease marked by certain signs only, and which spreads epidemically; and to say a malady is not cholera when all these signs are not present, or even if it does not spread when they are present. This view I am not prepared to endorse. The variability of the types of all other zymotic diseases is fully recognised. No one would deny a particular case to be one of diphtheria, or typhoid, or measles, because the symptoms were mild, or because all the symptoms of a typical case were not present; and it is only reasonable that the same breadth of view should be accorded to cholera. Then it would be recognised as what it really is—viz., a disease occurring at all times and in all countries, although not in the same degree of violence. Then futile endeavours to keep out the cholera by quarantine would be abandoned; then the erroneous idea that the disease is always imported from India would be no longer held; then there would be a better chance, especially on the Continent, of the axiom being acted upon—viz., that the incidence of cholera is always greatest in the most insanitary localities.

THE PREVENTION OF CHOLERA.

BY SURGEON-GENERAL A. C. C. DE RENZY, C.B.

As the history of cholera among the coolies proceeding to Assam by the Brahmaputra steamers is replete with instruction on the subject of the prevention of cholera, I think the subjoined facts will be opportune at the present time. The history extends over a period of nearly thirty years, and the facts are so well authenticated that they may be accepted with confidence.

From the very commencement of emigration *vid* the Brahmaputra the coolies suffered from frequently recurring and disastrous epidemics of cholera, and about the year 1870 the loss of life was so terrible that Government was forced to investigate the circumstances, and in 1872 an Act of the legislative council was passed prescribing arrangements in minute detail for the sanitary protection of the coolies. The cubical space on board the steamers, the ventilation and cleanliness of the vessels, the food, clothing, water-supply, and medical attendance of the coolies were provided for. The voyage up the Brahmaputra lasted about seventeen days, and during the trip the coolies were inspected by the resident medical officers of three intermediate stations. But, notwithstanding all the precautions taken, the epidemics continued to be terribly destructive; and it was not at all an uncommon occurrence for from fifty to seventy coolies to die from cholera in the course of a voyage. As the Government had adopted all the precautionary measures that had been suggested, and the sanitary arrangements had been again and again reported as satisfactory, the epidemics had come to be regarded as inevitable. They were supposed to arise from various mysterious causes which were beyond human control—as climate, malaria, predisposition on the part of the coolies, mental depression due to the pain of separation from friends, &c. The emigration reports from year to year abound with explanations of this kind. Such was the state of the question when my connexion with it began in December, 1877, on my appointment as Sanitary Commissioner of Assam. The question had great interest for me, for many reasons. The terrible sufferings of the people appealed strongly to my sympathies. The prosperity of the province, too, was closely dependent on the prevention of the epidemics. Labour was the great want of the province, and cholera every year swept off thousands of labourers who had been imported at a cost of about 100 Rs. per head. Moreover, during the ten years I had been sanitary commissioner of the Punjaub, I had had great experience of cholera, and I had been led to the conclusion that with proper precautions the disease might very easily be prevented. My views on this subject had been fully recorded in the Sanitary Reports of the Punjaub for 1868 and 1869.

As my researches had led me to believe that cholera is almost always propagated through water, in seeking for an explanations of the epidemics among the coolies on board the Brahmaputra steamers I naturally turned my attention, in the first instance, to the water-supply. But I was assured on all hands that the water-supply was above suspicion. The coolies, I was told, were supplied with water pumped from the great river, and especial care was taken to pump it only in mid-stream. The water was stored in fine iron tanks. And in confirmation of the opinion that in this case the water was harmless, I was told that the native crews of the steamers, some sixty or seventy in number, used only the Brahmaputra water, and they were singularly exempt from cholera. In the period of twenty years I was told that there had not been half a dozen cases of cholera among the crews. The information accorded entirely with my own later experience. I was on board steamers on several occasions when great epidemics occurred among the coolies, but the crews, although they lay at night on the deck amongst coolies, escaped entirely. There was no sickness of any sort whatever among them. These facts, which admit of the fullest attestation, made a great impression on me. But perhaps a still more singular fact remains. A very considerable number of Europeans have within the last twenty years gone up the river on the same steamers with the coolies. This class was composed of men, women, and children, for the most part connected with the tea industry. Strange to say, notwithstanding the great susceptibility of Europeans to cholera, these passengers, who lived on the same decks with the coolies and were only separated from them by a curtain during the daytime, were almost entirely exempt from cholera. I heard of only three or four cases in a period of many years. The European passengers used Brahmaputra water, clarified with alum and filtered. The coolies' water was treated with alum; but they often used the water before the suspended matter had time to subside. Since then the European passengers and the crews, who were exempt from cholera, used the Brahmaputra water (the crews used it without any clarification or filtration); it was quite certain that the epidemics among the coolies were not due to the use of that water. I was greatly puzzled to find a clue to the enigma, when it occurred to me one morning during the progress of an epidemic to get up very early, just as the coolies were coming down from their sleeping deck, and take up my position in the stern of

[7] Report on Cholera in Egypt, 1883.

Digitized by Google

the vessel where they stayed, and, without asking any questions, to observe their movements and doings. I very soon found what seemed to me a very satisfactory explanation of the mystery. I noticed the coolies crowding round two tubs half full of water, which were placed in the stern of the vessel, beside the entrance to the latrines. This water was intended to be used for ablution after defecation; but to my astonishment I saw the coolies rinsing their mouths with it, and even taking it away in their drinking vessels. I saw a woman washing her baby's clothing in a tub and coolies immediately after drinking the fouled water. The fact seemed to me so incredible that I brought Colonel (now Major-General) Sherer to witness the scene. Here, then, I surmised must be the explanation of the coolie epidemics. The water-tank had only one tap, and it was clear that 500 coolies, the number then on board, could not supply themselves with water from that one source; and as they had not the means of lifting water out of the river as the crew had, in their ignorance of the consequences they supplied themselves out of the polluted tubs. The tubs were replenished from time to time by a few bucketfuls of water raised by one of the crew, and when once they had been contaminated by the excreta of a coolie infected with cholera, they served for the culture of the virus and the circulation of it among other coolies. This discovery led me to study carefully all the arrangements connected with the supply of water to the coolies ashore as well as on board the steamers. I found the water-supply of the depôts in which the coolies were collected previous to embarkation in a most dangerous state. The depôts at Calcutta were situated in the northern portion of the town, to which the municipal water does not extend; but the Government orders were that a supply of drinking water was to be carried for the use of the coolies. The depôts, however, being about a mile from the nearest stand-pipe, the labour of carrying water such a distance was very great, and the temptation to evade the Government order was almost irresistible. As a matter of fact, on chemically testing some of the water I found conclusively that it was not municipal water, and that it must have been got from one of the innumerable filthy tanks in the vicinity of the depôts. Excepting the drinking water, all the other water used in the depôts was avowedly obtained from tanks of that character. One of these tanks was used for bathing and ablution by some 1500 coolies in the season, and as natives invariably rinse their mouths with the water they bathe in, the coolies must have swallowed the water of that tank very largely. These depôts were infested with cholera.

The water-supply of the depôt at Dhubri, a place some way up the Brahmaputra, was extremely bad. In the emigration season it was a mere stagnant backwater of the Brahmaputra, on the bank of which the cholera dead were buried, and, I may add, often disinterred by wild animals. I have seen vultures eating human remains and dropping fragments of them into the stagnant pool in which the coolies bathed, and at the same time took their drinking-water.

A third source of contamination was the water at the encamping grounds at which the coolies stayed on their march to the depôts at Dhubri; this water was in many places nothing but very foul ditch-water. At a place called Kanchrapara it was especially bad, as it was the effluent water of a washerman's village in which cholera is a perennial pest. I at once brought these matters to the notice of the Assam Government; but as the regulation of coolie emigration lay within the province of the Bengal Government, some time elapsed before any steps were taken to remedy the evils pointed out, and some of the evils remain in full force to the present time. The water-supply on board the steamers was improved; a pump was let into the side of the vessel and water was pumped into a long closed cistern provided with a number of taps, so arranged that it was physically impossible for a coolie to touch the contents of the cistern. Abundance of water was supplied for ablution fresh from the river, and the tubs were abolished altogether. At Dhubri a well was made, covered in and provided with a pump and a cistern with taps, but the work was done in a very unsatisfactory way, and in a letter of November 9th, 1882, from the deputy-commissioner, I learn that "the Dhubri well is not yet on a completely satisfactory footing; the water, though very much better, still continued to retain a slightly offensive smell until the other day, when its level sank altogether below the suction pipe of the pump, since which time the well has been out of use." In connexion with this state of the water-supply it is suggestive to note that in 1883 there were forty-three deaths from cholera among the coolies in the depôts at Dhubri.

In the Calcutta depôts makeshift arrangements, the best practicable under existing circumstances, were made, but under the system as it stands the most unremitting vigilance is required to prevent the use of contaminated water by the coolies. The water-supply at the encamping places remains as it was.

To recapitulate the changes made: 1. The water-supply on board the steamers was made satisfactory. 2. The water-supply at the depôts was improved, but is still far from satisfactory. 3. The water-supply at the encamping places remains unchanged, and is as bad as it can be. The improved water-supply on board the steamers came into operation in 1879, a year, I may add, of unparalleled mortality from cholera in Assam.

The following statistics show the annual death-rate among the coolies in the five years previous and in the five years subsequent to the change:—

Deaths per Cent. of Strength.

Previous to the Change.		Subsequent to the Change.	
1874	3·00	1879	0·81
1875	3·28	1880	0·42
1876	1·70	1881	0·88
1877	1·46	1882	0·65
1878	2·70	1883	0·65

In considering the above figures it is necessary to bear in mind that the saving of life during the last five years is considerably more than *prima facie* the figures represent. This arises from the fact that formerly when epidemics occurred it was the practice to land numbers of coolies at intermediate stations, and the deaths of these coolies were not included in the returns. In the last five years epidemics have been so infrequent that this practice has been very seldom resorted to. But taking the figures as they stand the reduction in the rate of mortality is very striking, and I think it impossible to attribute it to any other cause than the improvement of the water-supply.

I am bound, however, to state that Dr. Cuningham, the Sanitary Commissioner with the Government of India, disputes this conclusion. In his last report, that for 1882, which has just reached me, he thus expresses himself: "Para. 123. After enjoying a remarkable degree of immunity from the disease [cholera] for some time, the immigrant coolies again suffered on board the river steamers, and there were several outbreaks of cholera, those on the *Nepal* and *Sind* being attended with heavy mortality. The investigations which were made in the case of these and the other vessels concerned have only served to confirm the opinion expressed in former reports, and to show how hastily it had been assumed that the mere introducing of better arrangements for water-supply on board those steamers had almost entirely banished cholera from the coolies travelling on them." To this I would only reply that a reference to my Assam Sanitary Reports for 1878 and 1879 will show that I attributed the epidemics to defects in the water-supply at three points, viz.:—(1) On board the steamers, (2) in the depôts, and (3) at the encamping places. And as the defects indicated have been entirely removed at only one of the points, the results obtained are quite as much as could be reasonably expected. When coolies go on board infected at Dhubri it would be unreasonable to expect that the effect of the sanitary arrangements would prevent the development of cholera in them. All we have a right to expect is that the disease should be prevented from extending to those who arrive on board uninfected; that in fact these coolies should be put in the position of the native crews already referred to. And many of the incidents of the few outbreaks that have occurred within the last five years warrant the belief that this is attained. Since the water-supply on board the steamers was improved there have been three great epidemics of cholera in Bengal, the recruiting ground of the coolies, and Assam, the province to which they were proceeding, during 1879, 1882, and 1883. The epidemic of 1882 was the greatest that has occurred in Bengal for some years; but in spite of this the reduction in the rate of mortality of the coolies continued. It remains for Dr. Cuningham to assign a reasonable explanation of the reduction. In the earlier years of the experiment he attributed it to an abatement of epidemic influences, but that will not hold in the presence of the epidemics of 1882 and 1883.

It is, I think, greatly to be regretted that Government did

Digitized by Google

not comply with my earnest request to make the experiment complete, as I believe it would have thrown invaluable light on many obscure points relating to cholera. Emigration *vid* Brahmaputra is assuming immense proportions. Last year 20,000 coolies passed up the river. This great tide of human life affords unequalled opportunities for the exact study of cholera; but they are not turned to account because Government are taught to believe that the spread of cholera is governed by general influences which are altogether beyond human control.

Meanwhile I think the facts stated warrant the following conclusions:—1. Cholera has very feeble, if any, power of propagating itself through the medium of the air, otherwise the immunity of the native crews and the European passengers would be inexplicable. 2. Water is its favourite medium. When the water-supply is secure against contamination, it is hardly possible for cholera to become epidemic. The second conclusion is strongly confirmed by the experience of Fort William. This fortress stands in the midst of a community from which cholera is never absent, and scarcely a year passes that one or two cases of cholera do not occur among the troops, but since the water-supply was placed on a satisfactory footing the disease seems quite incapable of spreading. The Royal Commission of 1859 gives the death-rate of the garrison for a long series of years as 68·96 per 1000, and for the ten years ending in 1856 as 102·35 per 1000. In the ten years ending in 1882 the death-rate was only 9·45 per 1000. In many respects the sanitary condition of the fort is far from satisfactory; but the water-supply being safe, cholera is disarmed.

ON THE

INFLUENCE OF SMALL-POX HOSPITALS.

BY EDWARD T. WILSON, M.B. OXON., F.R.C.P.,
PHYSICIAN TO THE CHELTENHAM GENERAL HOSPITAL.

No. V.

IT cannot be too often or too clearly stated that the Report of Mr. Power to the Local Government Board in 1881 on the spread of small-pox in the neighbourhood of Fulham Hospital is the *fons et origo* of the theory now so warmly debated of the "distal aerial dissemination of small-pox." Sir Risdon Bennett does, indeed, say that "it singularly confirms the opinion he has entertained upon the subject in regard to the diffusion of contagion of small-pox from a central depôt of small-pox";[1] but I am not aware that he has anticipated Mr. Power by the publication of any such opinion, nor does he give the data on which it rests, unless they are contained in his answer to Question 4833, where the conveyance of smoke to long distances by the wind is cited as a parallel phenomenon; with the reservation, however, that "of course this opinion is more or less speculative"; and "what becomes of it [the particulate infectious matter] when it does pass out into the outer air I really cannot say, or what change it may undergo I cannot say."[2] Attempts have subsequently been made in various directions to utilise the theory for the explanation of outbreaks of small-pox, but as yet the facts are found to fit rather awkwardly into their assigned places, and refuse to lend themselves kindly in support of the new hypothesis. It is possible, of course, that in time facts may be forthcoming, sufficient in number and in significance, to prove that the infection of small-pox can be carried in an active state through the air to a distance of a mile or a mile and a half. All I would contend for at present is that such facts have not been recorded, and that the statistical tables on which so large a superstructure of theory has been raised are worthless when tested by a close and analytical investigation. The attention of sanitarians has at all events been fully awakened to the possibility of distal aerial infection; observation will be quickened, and well-observed cases must soon accumulate, if such are to be found; meanwhile there is a real danger that in some cases facts may be unconsciously twisted into conformity with a foregone conclusion.

In the present paper I had proposed to consider our knowledge of small-pox spread through the open air, independently of Mr. Power's report; and I had hoped that the eminent witnesses, representing every grade of the profession, who were examined before the Hospitals Commission, would have been able to furnish precise and trustworthy data on which their opinions had been based. Great, however, was my surprise and disappointment to find that on the important subject of distal aerial dissemination of small-pox, it is literally a case of *quot homines, tot sententiæ*, and that few indeed of the gentlemen under examination could give a reason for the faith that was in them. It will not be uninteresting, and it may be profitable, to examine the state of opinion at the present time on the limits of out-door aerial spread of small-pox as displayed in the pages of the Report.

Dr. Bingham, a medical officer for the Asylums Board, fixed the distance for infection at two or three feet;[3] Dr. Hill, of Birmingham, at five or six feet; Dr. Tatham, of Salford, at six to eight feet; and Dr. Grieve, a medical officer of the Asylums Board, at eight to ten feet."[4] Between ten and fifty feet we have: Dr. W. Squire, fifteen feet;[5] Dr. Brydges, thirty feet, but would recommend 100 feet as a sanitary zone;[6] and Dr. Markham, thirty feet[7] (Sir William Gull would consider thirty feet safe for a single case);[8] Dr. Gibbons, sixty feet;[9] Dr. Collie, seventy feet;[10] Dr. De Chaumont, whilst allowing that he has no exact evidence to go upon,[11] fixes 100 feet as a safe sanitary zone; Dr. T. Orme Dudfield[12] and Dr. W. Gayton[13] arrive at a similar conclusion. From 100 to 200 feet, we have Dr. Tripe insisting on 150 feet for any number of patients less than 100; whereas for 500 or 600 patients 500 or 600 feet and more might be required.[14] Dr. Munk,[15] as well as Dr. Gregory and Mr. Marson,[16] fix upon 150 feet as a safe distance; Dr. J. S. Bristowe comes in at 300 feet,[17] but has no facts. Sir William Gull also would have 300 feet[18] for 100 patients or more, but has no evidence of spread beyond thirty.[19] Beyond 300 feet we find no evidence until we come to Mr. A. Farr at 1320 feet,[20] and to Sir J. R. Bennett at 1500 feet,[21] who thinks, however, that infection, like small shot or smoke, might travel a mile or two.[22] Sir William Jenner would insist on 2640 feet round a small-pox hospital,[23] while Dr. George Buchanan,[24] Dr. Thorne Thorne, Mr. Simon,[25] and Mr. Power himself give in their adhesion to the theory that infection may be disseminated to a distance of 7000 or 8000 feet. Surgeon-General Bostock, a manager of the Metropolitan Asylums Board, tells us he once held that thirty feet was safe, but his faith has been shaken, and he now knows of no rule for regulating the distance.[26] Lastly, Mr. H. Stevens,[27] perhaps unduly stretching Mr. Power's hypothesis, says: "Taking as a standpoint that there is atmospheric distribution of small-pox as illustrated by what is believed to be the case at Fulham Hospital, if that atmospheric distribution of small-pox extends, say, over 300 yards, why not over as many miles, and it might happen with a favourable southerly breeze that a man at York would be hit by a small-pox pellet from the Fulham Hospital." This, however, is little more than an amplification of Sir J. R. Bennett's comparison between the passage of small-pox matter and the travelling of smoke from the Great Fire of London as far as Oxford, or his more startling belief[28] that small-pox poison might very possibly strike a man at a distance of fifty miles.

The large interval which will have been noticed as existing between 200 feet and a quarter of a mile indicates pretty accurately the effects of Mr. Power's Report, and will serve to distinguish the adherents of the new hypothesis of distal aerial infection from those who still cling to the old lines of belief. That small-pox infection can be communicated through the air is, so far as I am aware, denied by no one, and it is difficult to see the bearing of Sir Wm. Jenner's remark[29] "that the *onus probandi* should rest not on those who hold that it does spread by the air, but upon those who hold that it never does spread through the air."

The important question awaiting solution is not whether it ever does spread through the open air, but to what distance can the infection of small-pox be carried in an active state through the open air, and what circumstances, if any, tend to favour or retard its dispersion, or its powers of infecting? On these points there is abundance of theory, but a truly marvellous absence of facts. The voice of authority can

clearly do nothing for the settlement of this question, and the assistance of collective investigation might be invoked with much advantage. Well observed and accurately recorded facts can almost be reckoned on the fingers, and have never, so far as I am aware, been collected. A few were given by witnesses before the Royal Commission, but the instances of infection spreading over a greater distance than fifty feet are few in number, and not all so carefully recorded as their importance would seem to warrant. Dr. Thorne mentions a case which was in all probability caught "by reason of the bedroom window being only five feet from one of the windows of a room which was used for the reception of patients";[30] and in another case the disease was probably contracted from infected bedding exposed in a garden some eleven or twelve feet from a public thoroughfare.[31] Dr. B. W. Richardson is quoted[32] as having traced infection from a single case of small-pox to a distance of thirty feet; and Dr. Munk gives an instance of a person being attacked by the disease fourteen days after having watched a patient's entry to Highgate Hospital at a distance of forty-one feet[33]; the proof of this, however, is not so absolute as Dr. Munk would have us suppose; for it is impossible to say that there may not have been previous exposure to infection at a few feet or even inches in a London street, and especially in proximity to a small-pox hospital. Dr. Septimus Gibbon gives a case of a clergyman who (in his opinion) caught the disease through burying a corpse, though standing at a distance of sixty feet from the coffin.[34] Mr. Forshall quotes an instance of a student in St. Joseph's Monastery[35] contracting small-pox at a distance probably of from sixty to ninety feet; and Dr. Gayton gives a case[36] of a child which was supposed to have caught small-pox from sitting at an open window sixty-three feet from the hospital wards. For all these cases there is evidence more or less reliable; but the most remarkable instance, if we except a suggestion thrown out by Sir William Jenner, which could not have been seriously meant, that the small-pox matter might have been carried two miles and a half by the wind[37]—is one quoted at second hand by Dr. Haygarth, where ten out of twelve carpenters were supposed to have caught small-pox from a source of infection across a body of water at a distance of 1500 feet![38]

Apart from the examples in the Blue Book I am unable to point to any data pretending to accuracy, if we except the experiments performed by Dr. O'Ryan about a hundred years ago, and quoted by Dr. Haygarth, which would reduce the infectious zone of small-pox to a distance of from two to three feet. Sir John Rose Cormack, indeed, has given[39] the results of an interesting investigation by Dr. Bertillon into the spread of small-pox from an annexe of the Hôtel Dieu in Paris, during the year 1879, but unfortunately no measurements are given, and conclusions are based upon the fallacy common to this report, and that of Mr. Power, of reckoning the percentage of deaths to inhabitants, without giving heed to the units of which the population is composed. That small-pox depôts may become the centres of small-pox spread seems unfortunately to have been proved both in Paris and in London, but it is a mere *petitio principii* to say that "the history of the spread of small-pox in the vicinity of the annexe of the Hôtel Dieu is the history of spread by epithelial drift, so to speak, which no system of police can intercept,"[40] especially when it is further stated on the very same page that "the mode of diffusion was probably to a large extent by personal communication, a circumstance which prevents an estimate being formed of the extent to which epithelial drift disseminated the disease."[41]

In the recent outbreak in Hackney, which has formed the subject of an interesting paper by the medical officer of health, Dr. Tripe, the same fallacy is repeated of applying purely statistical methods to numbers utterly inadequate, and without sufficient examination of the component units. In the first six days, Dr. Tripe tells us the cases in Hackney were as follows:—

	Radius.							
	¼-Mile.		½-Mile.		Mile.		Outside.
Cases	20	....	15	....	16	....	14
Population ..	10,000	....	30,000	....	60,000	....	100,000
Percentage on population	2·00	....	0·50	....	0·24	....	·0014

But it must be borne in mind, as Dr. Robert Fowler very pertinently remarks in his speech before the City of London Union Guardians, "Homerton Hospital was actually built because these diseases seemed to be always making their home in the neighbourhood," and we are told nothing of the houses or of the populations which cover the areas so arbitrarily marked out. It may be mentioned also incidentally that whereas twenty-eight cases were deemed sufficient to infect the neighbourhood in some occult manner in 1884, no harm had been known to result from eighty cases[42] in a previous epidemic, and this in spite of the laundry being so close to the road that, while washing was going on, spray from the tubs has actually splashed into the face of the medical officer of health while walking in the street.[43]

Instances of complete immunity from small-pox at comparately short distances have been already mentioned in my previous papers, and they might be multiplied indefinitely, but although worth noting as negative evidence, they must yield before one well-authenticated fact. If small-pox can be proved in any one instance to have spread through the open air to a distance of 200 or 300 feet, instances of immunity at any less distance are of little worth for the objects of this inquiry. That small-pox is the most active and virulent of all the infectious diseases seems generally admitted; also that it consists of solid particles of inconceivable minuteness thrown off into the air from the pustules, the breath, and probably by the excreta, though it is a singular fact that even under the most favourable circumstances for such a means of spread no extension of the disease seems to have been traced to the drains of a small-pox hospital.[44] That this particular matter can attach itself to the persons and clothes of healthy persons, and so be carried to long distances, is beyond dispute; it may also float through the wards of a hospital, or be blown through corridors for many feet, as noticed by Sir J. Rose Cormack[45] in Paris, and by others, as at Bradford Hospital, where the long closed corridor at one time acted very like a spout. It may also, according to Mr. Simon and Dr. Macgillivray,[46] remain still active after three years' sojourn in the fomites of a deserted cottage. On the other hand, there seems no doubt that its power for harm is weakened by distance; and it remains to examine the circumstances which hinder or favour its dispersion through the open air. The actual quantity required for infection has not, as far as I am aware, been ascertained; nor has the extent to which small-pox matter may be oxidised and rendered inert by the atmosphere under varying degrees of moisture or dryness. Common-sense would suggest that, apart from its destruction *in transitu*, the infectious particles would be carried further in the direction of the wind than in any other direction, and Dr. Bond[47] has measured the distances to which infection was apparently carried from house to house in this manner in two cases which occurred in his district, and finds them to be 53 and 107 feet respectively. But it is distinctly stated in more than one instance of small-pox spread that it has not been in the direction of the wind prevailing at the infection period. In the recent outbreak at Hackney, described by Dr. Tripe, the infection did not go with the wind, but in the opposite direction. In the outburst at Fulham in 1881, Mr. Power does not suggest that the direction of spread was influenced by the wind—a still and foggy atmosphere, devoid of ozone, with occasional light airs from every point of the compass, was considered to be the chief agency on that occasion in disseminating the infective particles. That solid particles should travel against or, so to speak, under the wind is so improbable that it lends additional weight to the suspicion that more earthly messengers have been engaged in the infective process, even though we find a difficulty in detecting them; and it would appear as reasonable to describe dynamite as aerially disseminated because no dynamitard has been detected in the act and brought to justice, as to attribute the dissemination of small-pox round a hospital to atmospheric agencies wherever a difficulty occurs in accounting otherwise for the origin of the disease.

Observation and direct experiment are sorely needed to settle some of the most elementary points connected with the spread of disease. What degree of concentration, for instance, is required in small-pox virus for infection through the air? Is the immunity observed, say at 200 feet,

due to dispersion and simple dilution of the infectious particles, or to changes brought about by the oxidising processes in their passage through the air? Can we liken these particles thrown off by a patient to shot from a gun?[48] or should they not rather be compared to a charge of steam, or of hailstones, which in their passage would change their form or disappear? Mr. Power seems to think their transference is favoured by fog; and Dr. East, in a thesis which gained the gold medal of the University of Durham on "Hygrometricity, and the Spread of Specific Contagia," takes up a similar position, but no proofs are given. "At a time," he says, "when small-pox was not epidemic in the district, but there were over 100 patients under treatment in the Homerton Hospital, seven fresh cases came under my notice, all occurring within a quarter of a mile of the hospital; and although the most careful inquiries were instituted as to the possible modes by which the disease might have been contracted, none were discovered, and *I was forced to fall back on the assumption* that something had passed from the hospital to those affected, and *that the transit was through the air.*" Having then noticed that "a few weeks prior to the outbreak of these seven cases the hygrometric state of the atmosphere averaged eighty-nine degrees....., *I was led to the assumption* that there was probably in this fact a cause for the unusual incidence of small-pox in the neighbourhood about the hospital." On the other hand, we have Sir Wm. Gull[49] expressing an opinion that if the air were very dry the particles might travel further in an active state. Amidst such conflicting opinion it seems hard indeed to find any safe resting ground, and the Royal Commissioners have taken up an attitude so absolutely neutral as to leave the problem very much where they found it. "We feel," so runs the Report, "that so long as it is not proved that personal communication is adequate to the explanation of the whole spread of small-pox" (*when will this be possible?*), and so long as "distant atmospheric dissemination is not shown to be in the highest degree improbable, so long it is essential that in the construction and management of small-pox hospitals both sources of danger should be with the utmost care guarded against."[50] There may be reason to doubt whether these recommendations have been rigidly adhered to under the present regulations of the Asylums Board, by which fifty acute cases are admissible to each of the small-pox hospitals of the metropolis, but the admirable organisation recently introduced for the ambulance service in London, the increased care which is being exercised in the management of the hospitals devoted to infectious disease and the increased vigilance on the part of medical officers of health may, by excluding some of the gravest risks of infection, throw some light upon the spread which is admitted to take place from a small-pox hospital situated in a crowded locality. New facts will doubtless be forthcoming, and they must be carefully weighed, for the issues at stake are portentous. Should Mr. Power's theory be confirmed by additional and more accurate evidence, the position now taken up by the Asylums Board becomes untenable, and disaster could only be averted by a bold adoption of the circular hospitals, so admirably planned by Dr. J. Burdon Sanderson, and described before the Hospitals Commission, in which infection is consumed on the premises and its aerial dissemination rendered impossible.

I have already exceeded the allotted space, and must therefore content myself in conclusion by repeating a conviction, supported, as I believe, by the arguments and illustrations of my preceding papers, that no sufficient evidence has yet been adduced for the outdoor aerial dissemination of small-pox infection in an active state to a distance of 200 or even of 150 feet.

QUEEN'S COLLEGE, BELFAST.—The following have been awarded prizes at the termination of the summer session:—Botany—Senior Division: John Campbell, D. C. Smiley. Junior Division: C. E. Shaw, J. W. Moore, R. W. Haslett, J. M. Downer. Practical Chemistry: S. R. Collier, R. J. Ferguson, C. J. McVicker. Medical Jurisprudence: W. B. McQuilty, John Menary, J. K. Close, Andrew Buchanan and Samuel Moore (equal), A. S. Thompson. Midwifery: John Menary and C. W. J. Dunlop (equal), David Mark, Samuel Moore, Andrew Buchanan, Samuel Alexander and A. S. Thompson (equal).

A YEAR'S SURGICAL PRACTICE IN THE JAMSETJEE JEJEEBHOY HOSPITAL, BOMBAY.

By WELLINGTON GRAY,

PROFESSOR OF SURGERY, GRANT MEDICAL COLLEGE; SENIOR SURGEON TO THE HOSPITAL.

WITH the view of enabling the profession at home to judge of the kind and amount of surgical work that can be accomplished annually in a large native hospital in this country, I am induced to place before the readers of THE LANCET the following abstract, compiled from the returns and report of the Jamsetjee Jejeebhoy Hospital for the year 1883.

In this hospital one hundred and eight beds, or thereabouts, are set apart for surgical cases, and are in charge of the second surgeon, Surgeon W. K. Hatch, I.M.D., and myself. To give an idea of the circumstances under which we work I may mention that we are without skilled assistance of any kind; except when aided by the students during term time we have to attend to most of the petty details ourselves; while in cases of difficulty and doubt we have as a rule to rely on our own individual, or combined, judgment as circumstances may happen to require. I should mention, however, that fractures are put up and the first dressing usually applied to wounds by the apothecary on duty. We have a house-surgeon, a member of the subordinate medical department, but he is house-surgeon in name only; he does everything but house-surgeon's work as it is ordinarily understood in England and elsewhere. The enforced performance, by the surgeon himself, of work which in other hospitals is left to house-surgeons and dressers is no doubt for the benefit of the patients, but it takes up much of his time. The necessity also of having to depend so much on one's own unaided judgment in difficult or doubtful cases is not an unmixed evil: the practice at least engenders decision and self-reliance, courage in undertaking single-handed large and formidable operations, and readiness in emergencies. Until recently, too, nursing, as we now understand it, had no existence in this hospital; the sick, as regards the administration of medicines &c., were at the mercy of untrustworthy native servants; while the little comforts and attentions that add so materially to the welfare of a patient were unknown. All this is now changed, in the surgical wards at least, by the presence there of two of the All Saints sisters, who give their services voluntarily and gratuitously. Food and medicine are now given in accordance with instructions, the comfort of every patient is attended to, order is preserved in the wards, and in special cases urgent symptoms are watched for and brought to notice. It is hardly too much to say that patients who would have died under the old system recover under the new. I take advantage of this opportunity to bear testimony to the great and valuable services of the sisters.

The following list shows the number of admissions for different kinds of injuries during the year:—Fracture of the skull, 10; injuries of the spine and cord, 6; dislocations and fractures of facial bones, 12; fractured ribs, 15; fractures of the upper extremity, 81; dislocations of the upper extremity, 16; fractures of the lower extremity, 73; dislocations of the lower extremity, 12; multiple injury, 15; rupture of viscera, 3; burns and scalds (severe), 29; wounds of all kinds (severe), 198; snake-bite, 2; bites of animals other than snakes, 21. The greater number of these cases were of the ordinary kind, and presented no features of special importance. They were caused chiefly by falls, mill and street accidents, assaults, and the burns usually by the upsetting of paraffin lamps, women and children being the chief sufferers. Fractures in this country, as a rule, unite readily; a case of ununited fracture, indeed, is practically unknown in our hospital. In the treatment, we adhere generally to the old-fashioned simple splints, and have no reason to be dissatisfied with the results. Compound fractures, of which we receive many very bad cases, rarely give trouble, although I cannot say that we ever treat them after the strictly antiseptic method. The wound closes readily under ordinary dressings, combined with scrupulous cleanliness; and I am unable now to call to mind a single case during the past year where complications or delay have arisen.

One or two of the cases of multiple injury were of special interest. A man, aged sixty, fell head foremost down a

Digitized by Google

steep staircase, striking his chin against the ground. He sustained simple fracture of the right humerus and left femur, compound fracture of the lower jaw, and fracture of the base of the skull, due to both condyles of the jaw having been driven through the glenoid fossæ. He died shortly after removal from hospital by his friends. In the second case a man fell on his feet from the top of a palm tree fifty feet high. Both calcanea and the spine in the lower part of the dorsal region were fractured, and he also sustained Colles' fracture on both sides. One of the latter was compound, with such extensive injury of the soft parts as to necessitate amputation. This patient died on the second day. In a third case the injuries were depressed fracture of the skull, fracture of the pelvis, and of one rib; the patient recovering without a bad symptom. The three cases of ruptured viscera were due to street accidents, and were all rapidly fatal. The organs injured were respectively the bladder, stomach, and lung; the two latter occurring in children.

We rarely see snake-bite in Bombay, poisonous snakes being now few and far between. Both the cases recorded were bites of the echis carinata. One simply came to the hospital to be dressed, and went away before any very acute symptoms had supervened; the other was admitted twelve days after the infliction of the injury, which was close to the elbow. Here an abscess had formed, while the greater part of both feet had become gangrenous. There was no history of the mucous hæmorrhages usual in such cases. Under careful nursing, good food, and appropriate local treatment the patient, a boy of twelve, quickly got well. Several persons suffering from dog-bite came to the hospital to have their wounds dressed, the injury in some instances having been undoubtedly inflicted by rabid animals, as we learned after careful inquiry. So far, however, no case of hydrophobia has turned up in consequence.

Few of the numerous cases of wounds admitted were of any special interest or importance. In one case of homicidal injury the weapon, a long sharp-pointed knife, entered the left side of the chest between the ninth and tenth ribs, notched the lower edge of the lung, passed through the diaphragm, and transfixed both spleen and stomach. The injury to the latter was at one time recognised during life, in consequence of some of its contents having escaped through the external wound. It happened to be full at the time the injury was inflicted. Another victim of the same murderer received a stab in the lower part of the abdomen, the knife entering just internal to the anterior superior iliac spine, passing through the mesentery, and then downwards to the sacro-sciatic foramen, dividing both the internal pudic and sciatic arteries; the small intestine, which protruded, was uninjured. The patient, a man of eighty, died on the second day. In a third victim, who died before he reached the hospital, death appears to have been instantaneous: the knife was driven in transversely between the fourth and fifth left ribs to a corresponding point on the opposite side. In its passage it laid open the right ventricle and notched the back of the sternum. We admit a large number of lacerated and contused wounds of the extremities from the cotton mills and the streets. Strange to say, these mill accidents are not more common now, with nearly fifty mills at work, than they were twelve or fifteen years ago, when there were only half a dozen. The reasonable interpretation of this is, I take it, that the operatives have learned how to take care of themselves. The treatment of these ugly injuries by antiseptic irrigation and iodoform gives very satisfactory results. Of late I have tried, with equally good results, a dressing of iodoform on dry lint, then a thick pad of oakum, and a tight bandage over all, the wound, of course, having first been purified as far as possible. No sutures are used. This dressing is not disturbed unless the thermometer shows unequivocal signs of suppuration having occurred. Some of the most unpromising cases have healed admirably under this treatment.

That scourge, traumatic tetanus, often renders our most careful treatment of wounds of no avail. We have a pretty constant average of twenty-five cases annually. Last year, however, we had only thirteen, and the year before eighteen. I am convinced that more rigorous attention to cleanliness and sanitary surroundings is one main cause of the falling off, as far, at least, as those cases which originate in the hospital are concerned. Still, in spite of all precautions, it continues to occur from time to time under the most unexpected circumstances. The mortality for all cases averages 80 per cent. I may note here that last year we had not a single case of pyæmia, or, with one exception, of any form of septic poisoning, and this notwithstanding the fact that strict Listerism was not once employed in the treatment of compound fracture or accidental wound.

Surgical Diseases.—These comprised principally abscess, ulcer, sinus and fistula, venereal diseases, stricture, affections of the generative organs, joint diseases, and caries and necrosis. I cannot say that many of these differed, either in peculiarities or treatment, from the ordinary run of such cases. As regards venereal diseases, I may mention that for some years past we have had a Contagious Diseases Act in force in the city of Bombay; and as an important fact in support of the policy of repression, and one not sufficiently recognised, I think it desirable to mention that sloughing and phagedænic chancres, which under previous conditions were frequently seen, are now practically things of the past so far as this hospital is concerned. I recollect that in former years many horrible, and even fatal examples, of sloughing phagedæna used to be admitted; last year, on the contrary, not a single case was seen, nor in this year up to the present date. In speaking on this question here I must be understood as holding to the belief that infection derived from a phagedænic chancre is a potent factor in the reproduction of that form. Civil and military statistics in this presidency tell us conclusively that if the Contagious Diseases Acts have accomplished nothing else, they have at least resulted in modifying the severity of primary lesions. Amongst affections of the generative organs, I have met with three cases of acute inflammation of the tunica vaginalis; or acute hydrocele it might be called. The disease was of only a week's duration, with great pain and tension, accompanied by fever; the tumour in each case was quite as large as a cocoa-nut; the fluid contents were slightly turbid, and the serous surface was covered with a thick velvety coating of lymph. With a free incision and a drainage-tube recovery quickly followed. Should further opportunities occur I shall investigate the subject more closely. In none of the cases was I able to assign the inflammation to any definite cause. A case of scrotal abdominal hæmatocele which occurred during the year has already been reported in THE LANCET of Sept. 22nd, 1883. One case of acute glossitis, ending in abscess, was treated.

Operative Surgery.—Last year there were performed 152 major and 2519 minor operations. Of large amputations 37 were performed, as shown in the accompanying table:—

	Primary.	Cured.	Died.	Secondary.	Cured.	Died.	Disease.	Cured.	Died.
Thigh	1	1	—	1	—	1	3	1	2
Knee	3	3	—	—	—	—	3	1	2
Leg	6	5	1	—	—	—	5	4	1
Foot	3	3	—	—	—	—	2	2	—
Shoulder	1	1	—	—	—	—	—	—	—
Arm	3	3	—	—	—	—	—	—	—
Forearm	4	2	2	—	—	—	—	—	—
Hand	2	2	—	—	—	—	—	—	—
Total	23	20	3	1	—	1	13	8	5

Nearly all the primary operations were for railway and machine accidents; the disease cases for joint affections and mycetoma. The first point to be noticed in this table is the disproportion between the mortality in primary amputations as compared with that after the operations for disease. The secondary thigh amputation was for a smash of the limb just above the knee, with compound fracture of the leg, the result of a tramcar accident. The patient declined operation till it was too late, and in a few days after it was performed he died of exhaustion. The same thing happened in two of the amputations for disease: the patients and their friends refused consent till the favourable moment had passed, and then pressed for operation—death following from exhaustion. All three were cases of knee-joint disease. Carden's operation was the one invariably chosen for the knee amputations of the year. We have given a fair trial also to disarticulation, but have come to the conclusion that the latter gives far better results, both as regards the process of healing and the condition of the stump. The one successful operation for disease was for mycetoma. The two fatal cases were for elephantiasis of the leg, with ulceration, and for knee-joint disease respectively: the first died from exhaustion, and the second from pulmonary thrombosis the day after operation.

Digitized by Google

In the fatal case of primary leg amputation death resulted from spreading gangrene; but why the disease should have supervened in this particular case we were never able, after the closest investigation, to discover. The patient was young and healthy, the injury was quite local, and he was placed after operation in exceptionally good sanitary circumstances, far removed from any source of septic infection. The disease amputations were all for advanced caries of the ankle-joint and tarsus. Death in the unsuccessful case was due to tetanus. In one instance, although the patient suffered from phthisis in addition to the joint disease, and was much emaciated and reduced in strength, he yet made an excellent recovery, the wound healing by first intention. So complete, indeed, was the recovery, that when he came to hospital later on to show himself and to have his wooden leg altered, I found some difficulty in recognising him; the lung symptoms had to a great extent subsided, and he had grown quite fat and strong. I regard this example as additional proof, if such were needed, that the removal of a diseased limb in the case of a phthisical subject is, when judiciously resorted to, sound surgery. There is nothing particular to note about the foot, shoulder, and arm amputations: all did well. In the two fatal cases of amputation of the forearm death was due to other injuries; in one instance to fracture of the spine, and in the other to severe burns of the chest and abdomen. The injury to the arm in the latter case, as well as the burn, was caused by an explosion of gunpowder. In the treatment of amputation wounds I have tried many experiments, with the object of devising a trustworthy, cheap, and easily prepared antiseptic dressing. A good number of my experiments have succeeded, the wound healing by immediate union or by first intention; some have, however, failed. When sufficient materials have accumulated I shall communicate a paper with the results of my experience. I may say here, however, that the antiseptics which I regard with most favour at the present moment are corrosive sublimate and iodoform.

Lithotomy and Lithotrity.—Lateral lithotomy was performed twenty-six times during the year; seventeen of the patients were from fifteen to sixty years of age, the majority ranging from eighteen to twenty-five. Nine cases were children from three to fourteen. Of the adults two died, one aged sixty from kidney disease (cystic kidney), the other, a young man of eighteen, from exhaustion. In the latter case the symptoms had existed from childhood; the stone was large and the bladder much diseased, while the patient himself was ill-developed, more indeed like a child of ten, and was worn out by pain and irritation. One child died of small-pox, contracted when nearly convalescent after the operation. Nearly all the calculi were lithic acid; the largest weighed five ounces and nine grains, and the patient made a good recovery. The suprapubic operation was found necessary in one case, a very small, ill-developed girl of six. The stone, a large and very hard lithic acid one, was actually too bulky to pass the pelvic outlet. An attempt was made to crush the stone, but it resisted our strongest lithotrites. The high operation was therefore performed, but the child died exhausted on the fourth day. Lithotrity has seldom been practised in this hospital, not at all last year. Why this should be so I cannot precisely say. Hospitals are no doubt guided much by tradition as regards treatment, and our traditions favour lithotomy. We have reason, besides, to look upon it with favour, our results for many years past having been uniformly excellent—better than lithotrity. The old crushing operation, with many sittings, was never liked by native patients. They always expect to be cured at once, and we used to find great difficulty in inducing them to submit to the necessary delay; they could not understand the reason for repeated operations. Accordingly they much preferred cutting as more expeditious and, as far as our experience went, equally safe, if not safer. Even with the single-sitting operation, which, by the way, our native patients appreciate, our experience remains the same. Of the two operations, the mortality in 1882 was actually greater for crushing than for cutting. In the present year, however, I have taken to single-sitting lithotrity in adults, and so far with most satisfactory results.

Herniotomy.—This operation was performed on nine occasions for strangulated inguinal hernia; six cases recovered, and three died. In one instance death was due to tetanus, which came on after the patient was pronounced out of danger from the operation. In a second fatal case, a man of sixty, the gut was gangrenous, and, although the patient survived for nearly three weeks, he eventually succumbed to exhaustion. The third death was due to exhaustion, the patient being almost moribund at the time of operation. Cases of strangulated hernia, when operated on in time, do surprisingly well here. Could patients be only induced to come early enough for treatment the mortality would, I am convinced, be very small. In my experience peritonitis, even in the worst cases, is very rare; and a reduction without opening the sac is quite exceptional. As a rule, we now ligature and remove the sac. The radical cure of hernia by ligature and excision of the sac, with closure of the external ring by silver sutures, was undertaken in three cases; two of these were successful, and the third died of tetanus when well advanced towards recovery. The isolation and removal of the sac is one of the most troublesome operations I have performed.

Sixteen large tumours were removed, amongst them two scrotal ones. Neither of the latter was very large, and both cases did well. As compared with its frequency in Calcutta, the disease on this side of India is very rarely met with. There was nothing very remarkable about any of the others, with one exception, that of a sebaceous tumour of the scalp, which was large enough to hang down between the shoulders. Amongst miscellaneous operations, external urethrotomy was performed on three occasions, with successful results; castration, twice for cystic testicle and twice for hæmatocele; tracheotomy three times; and the penis was thrice amputated for epithelioma. In two of the latter cases the disease was so far advanced as to necessitate the removal of the whole organ. In one of them the scrotum was involved, and this, with both testicles, was also removed. The urethra in each case was fixed in the posterior angle of the wound, just in front of the anus, and with highly satisfactory results. Abdominal section was once performed for intestinal obstruction, supposed to be caused by the pressure of a large solid ovarian tumour on the ascending colon. The real cause of obstruction, however, was found to be a cancerous growth, involving the cæcum and ascending colon. This was removed and an artificial anus made, but the patient quickly succumbed. There was a large solid ovarian growth on each side. The case was in charge of my colleague, who will no doubt in time publish the particulars. During the year I met with one case of epithelioma of the upper lip in a woman.

Minor Operations.—Our hospital practice in this department of surgery is not inconsiderable. Last year, for example, there were 550 abscesses incised, 346 hydroceles tapped, forty-six fingers and toes amputated, thirty-seven circumcisions performed, and 1391 teeth extracted. Many other operations, too numerous to mention, were also done. As regards hydrocele, the treatment by injection of tincture of iodine is still successfully followed here; it is, at least, an exceedingly rare occurrence for one of our patients to present himself for a repetition of this treatment. Most of the minor operations are done by the senior students under my superintendence.

A word or two about *Anæsthetics*. Here we invariably use chloroform. It is administered on an average 500 times yearly, and, as far as I have been able to discover, we have not to record a single death against it. I have seen, however, more than one narrow escape. No apparatus is employed; it is given from a cone of lint held over the mouth and nose. Native patients come easily and quickly under its influence, and it is quite unusual for them to suffer from sickness after it. A few years since ether was largely tried, but had to be given up in consequence of the very severe and troublesome bronchitis which generally followed. I need hardly say that we are perfectly satisfied with chloroform and with our method of administration.

This short and imperfect account of a single year's surgical work in an Indian native hospital will at least show the profession at home that we are not idle, nor, in spite of many drawbacks and difficulties, I may venture to add, unsuccessful. There is here a large, and to a great extent unworked, field for scientific investigation and experiment, and my only regret is that, from causes unnecessary to mention, we have been able to accomplish so little.

ON the 31st ult. the Colchester new main drainage works, which have just been completed, were handed over to the Mayor of the borough, and accepted by him on behalf of the corporation. They have been constructed at a cost of £55,750.

A CASE OF

SYPHILIS, AND SOME OF ITS EFFECTS.

TWO CASES OF INFECTION THROUGH THE FŒTUS, AND LOCOMOTOR ATAXY.

BY THOMPSON FORSTER, M.R.C.S., L.S.A.,
FORMERLY HOUSE-SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

L. J. F——, a dark, phlegmatic, temperate man, aged thirty, of gentle disposition, fair intellectual power, and highly moral, excepting for a short time, sought advice in September, 1862. He had a small hard chancre, which was followed by enlarged hard glands in the groin. He remained in this condition for some weeks, when the glands gradually resumed their normal condition. In January, 1863, he suffered from slight sore-throat. The local treatment consisted in the application of nitrate of silver; mercury and iodide of potassium were prescribed, which were continued for four months, long after all symptoms of the disease had disappeared. From 1863 until the spring of 1882 he had no symptoms of syphilis. In January, 1865, he married a very healthy, strong girl. In April she had sores on the vulva, aborted in May, had ulcerated sore-throat, and was covered with a copper scaly rash. In May, 1866, a seven months' child was born, with dry wrinkled skin, and soon after had sore mouth, coppery rash, rough skin, snuffles, &c., and died in ten weeks. The mother gradually acquired, and continued to have, fair health, until May, 1868, being then pregnant, when she was suddenly seized with difficulty of breathing, and died before any medical aid could be obtained.

In May, 1872, L. J. F—— married again. His second wife was also a very healthy girl. She became pregnant in June, suffering from copper rash, debility, loss of flesh, and miscarried in November. The child lived a few hours only, was shrivelled, small, and apparently diseased. The mother recovered slowly, but did not become pregnant for some years. After consultation, although the opinions were opposed to it, I put her under a course of mercury and iodide of potassium in 1876, as well as her husband, for over two months. They both regained good health. In 1877 she became pregnant a second time, and in July, 1878, a healthy eight months' child was born. In January, 1879, she again became pregnant, a healthy child being born at full time in March, 1880. In January, 1881, L. J. F—— had a fall, the effects of which he felt for a time, and then they passed off. In the spring he began to show symptoms of locomotor ataxy; in the following winter numbness of the end of the thumb and finger, hesitation in speech, slow walk, loss of knee action, &c., were well marked. The symptoms rapidly increased in intensity, and he died in the autumn, after having suffered very severely from delusions. It was very difficult to make his immediate friends understand the gravity of the case. At a consultation in the spring the prognosis was rapid increase of disease and probable death.

Remarks.—I think this case worth recording from the length of time it was under observation and the many interesting points exhibited—namely, the effects of the mercury and iodide of potassium; the infection through fœtus in both cases, though modified in the second; the caution necessary in giving an opinion as to marriage after syphilitic infection; the curious way that L. J. F—— remained healthy personally as far as could be seen for the long period, yet infecting two others at different periods; his attack of locomotor ataxy and death, in spite of free treatment with mercury and iodide of potassium. During the case two physicians and one surgeon, very eminent in London, were consulted.

A NEW METHOD OF TREATING SPRAINS.

BY THOS. L. SHEARER, M.B., C.M. EDIN.

EVERYONE who has had sprains to treat in practice must have been at times annoyed by the slowness of recovery of the injured part. This is not so important in hospital patients, many of whom, enjoying the life diet &c. of these institutions, do not object to prolonged treatment; but in the wealthier classes in private practice the surgeon must often hear complaints that the injury is so long in recovering. I have had a considerable number of sprained limbs to treat, and, after employing the usual plans of treatment, was led to adopt a new agent—clay. The clay is simply that used for making bricks, free from gravel, dried, and finely pulverised in a mortar. The powdered clay is mixed with water so as to form a thick and moist consistence. This is spread on muslin to the depth of a quarter of an inch, and applied entirely around the part. Over this is placed a rubber roller bandage, just lightly enough to keep the dressing from shifting and to retain the moisture. At the end of twenty-four or thirty-six hours the dressing must be renewed. It may be well to relate a few cases by way of illustration.

CASE 1.—Mr. T——, aged fifty-eight, was thrown from his carriage, and in addition to other injuries, received a severe sprain of his ankle, completely incapacitating him from motion of any kind. The part was hard, swollen, intensely painful, and throbbing. The dressing, as above described, was applied, and in twenty-four hours the pain was almost entirely gone, and the swelling to a great degree had subsided. The dressing was renewed daily, and in eight days the patient was going about attending to his business. The part was free from pain and natural in every respect.

CASE 2.—Mr. McC——, aged sixty, slipped and sprained his ankle so severely as to confine him to bed. The treatment was the same as that employed in Case 1, and the patient was out and walking in the streets in ten days.

CASE 3.—Mrs. A——, aged seventy-four, in stepping from her carriage missed her footing, and twisted her left knee violently. In a few hours the part was greatly swollen, hot, throbbing, and painful; the least motion of the joint caused excruciating agony. Pressure over the ligament was especially painful. Next day I saw the patient, and applied the clay dressing. The day after the patient was much easier, the swelling rapidly subsiding. The pain was almost *nil*, and movement of the part was not followed by such distress. The lady was walking in her house in ten days after the injury.

Dr. Hewson, of Philadelphia, about ten years ago introduced earth as a means of treating fibroid tumours of the uterus, and also sprinkled burns with the dry earth, claiming that the tendency to deformity in the latter cases was lessened. However, I am not aware of sprains being previously dressed with clay, and it was thought as well to lay the efficacy of the method before the profession. A number of other cases could be cited, but they would simply be a repetition of those already mentioned. While speaking of clay, it would, perhaps, not be amiss to state that the powdered dried earth sprinkled on the surface of an ulcer, and adhesive straps applied over it, is a capital dressing for cases which are so weak that even the weakest ointments tend to break down the granulations.

Baltimore, U.S.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nullas autem estalia pro certo noscendi vias, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

BONY ANCHYLOSIS OF LOWER JAW; REMOVAL OF A WEDGE-SHAPED PIECE OF BONE ON EACH SIDE; RECOVERY, WITH GOOD MOVEMENT OF JAW.

(Under the care of Mr. SYDNEY JONES.)

FOR the following notes we are indebted to Mr. W. H. Battle, surgical registrar.

T. A. H——, aged eighteen, was admitted on Nov. 22nd, 1883. Family history and previous history good. When between two and three years of age patient fell from a window on to a stone pyramid. The medical man called in did not say for certain whether the jaw was broken or not, but treated the case as if it had been a fracture. When the bandages were removed it was found that the lower jaw was fixed and the patient was unable to open his mouth; there was, however, a small interval between the teeth in front, and this, it would seem, was maintained by corks in the course

Digitized by Google

of treatment. Nothing more was done until the boy was about seven years old, when he was weekly put under chloroform and his jaws were separated a little each time, and boxwood plugs placed between them in the intervals. This treatment was continued for two or three months, at the end of which time the jaws were separated about half an inch in front, and the upper and lower back molars were just separated, but no more. The boy was, however, quite unable to move the jaw. He discontinued the use of the plugs after about another month, and the jaws gradually began to close again from behind forwards. Six months before admission the bicuspids were separated by about one-eighth of an inch, but afterwards quite closed. About three weeks before admission patient had some severe aching pain extending down the regions of the ascending rami of the jaw, lasting for two or three days, at the same time he noticed that several small pieces broke off his molar teeth; but he had noticed this before the pain, and the same thing occurred a week before admission, when he had a second attack of pain. His lower jaw had not grown in proportion to the rest of the face, and in consequence it appeared to recede more and more as the upper part of the face developed. Latterly he had taken nothing but liquid food, but when taking solid food he used to rub it between the tongue and the teeth or hard palate.

On admission it was noted that the patient was well nourished, but with a very small chin, and the lower jaw small, out of proportion to the face. He complained of inability to open his mouth. The lower jaw was firmly fixed, and no movement of it could be obtained. The upper incisor teeth projected about half an inch in front of the lower ones, leaving an opening through which the patient took his food. On the right side the upper canine teeth projected in front of the lower ones. The first upper bicuspid was wedged between the lower canine and first bicuspid, and seemed to be perfect. The second bicuspid was similarly wedged between the two lower bicuspids, but the greater part of the crown was gone. Behind this there were no teeth in either jaw, the gums being closely approximated as far back as the alveolar processes of the jaw extended; behind the alveolar processes an interval was present. On the left side the upper canine was free and some distance in front of the lower one; the lower canine was wedged between the two upper bicuspids, and all these teeth seemed to be entire; behind these there were what appeared to be two other teeth, but whether belonging to the upper or lower jaw was not apparent. As on the right side, the gums were closely approximated, and where the alveolar processes ended a similar interval existed. The two lower central incisors were absent, having been removed whilst the patient was formerly under treatment. Over the chin there was a linear scar, marking the position of the wound received at the time of the accident. On passing the finger backwards along the lower border of the jaw a notch could be felt at a point which corresponded to the junction of the horizontal and vertical portions, the latter projecting downwards a little. There was some pain on pressing over the right temporo-maxillary articulation. Otherwise the patient was healthy.

On Dec. 12th, the patient having been put under the influence of an anæsthetic, Mr. Sydney Jones, after removing some of the teeth to facilitate the introduction of the lever between the jaws, cut down on the temporo-maxillary articulation on the right side by means of an incision an inch and a half in length, and just below and parallel to the zygoma. In cutting down to the bone several vessels were divided and ligatured. After division of the masseter muscle the periosteum was separated from the bone; the condyle being firmly anchylosed to the zygoma and temporal bone, and quite immovable. A triangular wedge-shaped piece of bone, the base of the wedge being behind, was removed from the condylar process by means of the saw. The lower jaw was then found to be movable to a slight extent, and after the introduction of a lever between the jaws, the interval, which had only been half an inch, was increased to one inch and a half. The lever was then placed between the jaws on the left side, and they were likewise found to be capable of separation. On this account operation on the left side was postponed. A drainage-tube was inserted, the wound closed by interrupted silk ligatures, and dressed with iodoform dressing. Next day the patient complained of pain in both temporo-maxillary articulations, but was otherwise comfortable. Morning temperature 98°; evening 101·4°. On the afternoon of the 14th some slight forcible movement of the jaw was made, and after that, until the 18th, there was a pretty constant oozing of blood from the wound; on that day two of the stitches were removed, and the wound was injected with iced carbolic solution, iced carbolic solution being used also as a dressing. As this did not arrest the hæmorrhage, the remaining stitch was removed on the 19th, and the wound was thoroughly cleansed with iodoform. Before the wound was cleansed the temperature on several occasions had been above 100°, though not higher than 100·8°. On the 17th the patient spat some blood, but on that day only, and there was no clear evidence of its source. On the 20th there was a good deal of pus of a brownish colour, without odour.

From this time the progress was satisfactory; the wound gradually closed with diminishing discharge, and after about a week the patient was able to move his jaw voluntarily, though with some pain in the temporo-maxillary regions, greater on the right side. Chlorinated soda lotion was used as a dressing, and strapping to approximate the edges. At noon on the 21st the temperature was 101·2°; in the evening 100·4°. On the 22nd and 23rd, in the evening 100°. With these exceptions it had been normal or subnormal.

On Jan. 14th, 1884, the wound was completely healed. There was no pain on movement of the jaw, but the range of movement not having been so well maintained as the patient wished, it was decided to operate on the left side. The patient having been again anæsthetised, Mr. Sydney Jones proceeded to perform an operation on the left side similar to that which he had previously done on the right. In making the incision several small vessels required ligaturing, and on separation of the periosteum a similar condition of anchylosis was disclosed. By means of a saw and a bone forceps, a wedge-shaped piece of the jaw-bone was removed, with the effect that the jaws could be separated much more widely than had before been possible, and this opening was further increased by the use of the gag. The wound was closed with silk interrupted sutures, a drainage-tube inserted, and dressed antiseptically.

The patient had a good deal of pain for several days after the operation, and his face swelled much on the left side. On the 19th the stitches were very tense and there was some distension of the wound, which was filled with clot and slightly offensive in odour; there had been a good deal of oozing. Iodoform dressing was applied. The temperature on the 17th and 18th varied from 98·4° to 101·6°. On the 19th the morning temperature was 97·2°, evening temperature 99·6°. Slight oozing continued until the 21st. On the 25th the wound was looking healthy and the surrounding inflammatory swelling was much diminished. The jaw could be moved much more than before operation and without pain. There is slight displacement of the jaw to the right side. By the 31st the swelling of the face had disappeared and the wound was rapidly filling up.

From this time the patient frequently separated his jaws with the handle of a spatula. By this means the range and movement had increased. On Feb. 9th movement was entirely vertical and to the extent of about an inch, no lateral movement being possible. The masticating power was rather feeble, but this also had shown improvement, and the wound had healed. After Jan. 19th the temperature did not exceed 99·8°.

GUY'S HOSPITAL.

TWO CASES OF LUPUS; SCRAPING AND APPLICATION OF CARBOLIC ACID.

(Under the care of Mr. BRYANT.)

CASE 1. *Lupoid Papilla of Nose; Scraping and Application of Carbolic Acid; Cure.* (From notes by Mr. Sandol.)—W. S——, aged thirty-two, a soldier in the Life Guards, was admitted on March 7th, 1883. His mother died of cancer. Patient had had gonorrhœa, but not syphilis. He had recently returned from the Egyptian campaign. He first noticed two warts, one situated on the upper third of the bridge of the nose, and the other on the inner side of the nose. These first appeared three months before admission, and in boxing the warts got frequently knocked off, and ultimately an ulcer formed. On admission there was an irregular pinkish-looking papilla on the inner left side and upper third of the anterior surface of the bridge of the nose. This was covered with dry scaby crusts. Under chloroform the papilloma was scraped with a scalpel. There was very little bleeding, which was quite stopped by carbolic

Digitized by Google

acid applied on little bits of lint. The nose was dressed and the surrounding parts washed with glycerine. Under the microscope sections of the material showed slightly enlarged papillæ covered with a somewhat thick layer of cuticle. All the tissue beneath the *rete* layer was thickly infiltrated with granulation tissue, especially round and between the vessels of the corium. It was indistinguishable from a well-marked case of lupus. The enlargement of the papilla was not at all a marked feature. On March 26th the patient left the hospital with the wound healed, except a spot about the size of a pea.

CASE 2. *Lupus of Face and Left Forearm; Scraping and Application of Carbolic Acid; rapid Convalescence.* (From notes by Mr. Fowler.)—Charles A——, aged fifteen, was admitted on Sept. 6th, 1882. His family were healthy. Two years ago he first noticed some little boils on the right side of his face; they spread quickly to the other side. He was in the London Hospital, where something was done under chloroform, and he was discharged cured. The disease returned, and he had been an out-patient to the London Hospital. On admission the patient had lupus of the face. The disease covered the nose, which was much flattened. It had spread thence symmetrically over both sides of the face, reaching down as far as the hyoid bone. On the right side it extended a short distance between the lobule of the ear and the mastoid process, and on the cheek reached up to the outer canthus, opposite which there was a large elliptical scab about an inch across. Opposite the angle of the lower jaw there was another smaller scab. On the left side it did not extend quite so far behind the ear or on to the forehead. There was a very small part on the chin free from disease, and on this was a small scab about the size of a pea. The angles of the mouth were rounded, the upper lip was everted, and the mucous membrane resembled the neighbouring skin, being whitish and shining. The lower eyelid was everted. The disease was marked by a well-defined red and swollen border. On the back of the left hand was a circular patch of granulation tissue, which was beginning to heal in the centre; it extended to the outer border of the hand and along the little finger as far as the first inter-phalangeal articulation, and along the ring finger for some distance. The metacarpo-phalangeal joint of the ring finger was destroyed, but movement was still left. The metacarpo-phalanx was destroyed, and the finger much thickened at its base. On the left forearm was a raised ring of granulations running round the wrist. On the arm was another patch. On the 12th, under chloroform, the left half of his face was scraped, and afterwards touched with pure carbolic acid and dressed with compound tincture of benzoin. On the 26th the right half of the face was similarly treated, but acid nitrate of mercury was used instead of carbolic acid. On the 29th the part touched with nitrate of mercury had sloughed. Part of the slough was removed. On Oct. 5th, on each side of the face and just below the zygoma was a long triangular raised area of granulation tissue; the granulations were red, uniform, and healthy. The nose and adjacent part of each cheek were covered with cicatricial tissue. The hand, forearm, and arm were about the same as when admitted. The wounds were dressed with cod-liver oil. On the 12th he was discharged. A fortnight later the wound on the cheeks was gradually cicatrising.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Surgical Section of the Academy was held on May 9th.

The following living specimens were exhibited:—Two cases of Excision of the Knee, in youths aged eleven and thirteen years respectively, by the President; cases of Amputation at the Hip-joint, by Mr. Stokes and Mr. O'Grady. Card specimens were shown by Mr. Colles, Mr. Stokes, Dr. M'Ardle, Mr. Kendal Franks, Mr. O'Grady, and Mr. L. H. Ormsby.

Mr. L. H. ORMSBY read a paper on Acute Traumatic Malignancy, and detailed the history, progress, and result of four instructive cases in connexion with the subject. He endeavoured to prove that a distinct clinical set of malignant tumours rapidly following local injury might be classified under the term "acute traumatic malignancy," believing, as he did, that occasionally, under the stimulus of severe local irritation, the tissue elements, which under favourable circumstances would assume only the necessary activity for healthy repair, might take on a more prolific cell formation, ending in a very rapid development of malignant disease belonging to either the group of sarcomatous or carcinomatous formation. In his opinion, however, local irritation was not alone sufficient to account for the rapid development of such tumours, but it was an important factor when there was already an inherent tumour-forming diathesis present in the constitution and the local irritation or injury was accidentally received.—Mr. THOMSON, referring to the clinical aspect of the cases, said, if an operation were required at all, it should be done at such a distance from the seat of the disease as would render the return of it as remote as possible. In the great majority of those cases the disease returned sooner or later. That evening was exhibited a case in which Mr. Stokes had nearly three years ago performed amputation of the hip-joint with satisfactory result. The patient had been suffering from one of these tumours consequent on an injury to the thigh. After consultation the limb was amputated. Though the patient was in an extremely low condition, the result was satisfactory, and so improved did he now appear that there was no indication of a return of the disease. When the tumour existed in the tibia, the question was whether the patient should be subjected to amputation at the hip-joint or merely amputation through the shaft of the femur.—Mr. ORMSBY, in reply, said that the object to be aimed at was to go as high as possible above the seat of the disease. He had amputated at the upper third of the thigh, being afraid of subjecting the patient to the risk of amputation at the hip-joint.

Dr. E. H. BENNETT read the notes of a case of Excision of the Knee, having exhibited the patient at a previous meeting. The child, a girl, is now ten years old, and a period of nearly two years has elapsed since the operation. From early childhood she suffered from disease of the knee, which had led to suppuration with open abscesses. These healed, leaving the knee bent. She was then able to move about, although very lame, until six months before her admission to Sir Patrick Dun's Hospital, when the disease became re-established, and she could move only with the help of a stick, being unable to bear weight on the joint. Then sinuses appeared, and the child's health began to fail. The ordinary operation was performed, a great deal of bone being of necessity removed. The limb was placed in a plaster-of-Paris bandage, and the wounds closed, but the bones failed to unite. After seven months' treatment health was restored, and the limb could be flexed to a right angle, while the girl could stand on it without other support. She walked with trivial lameness, and could go up and down stairs without any difficulty.—Mr. THORNLEY STOKER said the best tribute he could pay to Dr. Bennett's observations would be to endeavour in his next case of excision of the knee to obtain a movable joint or a movable limb without a joint. He asked whether it was from theory or experience that the sections through the tibia and femur were made. It seemed better to fashion the surfaces so as to resemble naturally the upper surface of the tibia and the lower surface of the femur.—Mr. CORLEY thought that success in excision of the knee-joint depended on securing immobility, and on the apparatus employed for that purpose. If fibrous union could be secured without endangering the patient's chance of life, the proposed procedure would be justifiable, but the evidence would not justify their looking for a rigid limb.—Mr. THOMSON contended that the force of Mr. Corley's objection depended upon whether or not the wound was suppurating. Given a wound without suppuration, union almost immediately ensued. If the cut surfaces of the bones were closed in and the wound made subcutaneous, he saw no danger from commencing passive motion of a mild character at an early period. There was nothing impossible in looking for a movable joint, the surfaces being fashioned to resemble the original surfaces.—Mr. ORMSBY attributed the result more to good luck than good guidance. If passive motion were set up too soon in strumous subjects, the end would be amputation. At the same time he did not see why there should not be motion in the knee-joint as well as in the elbow-joint following resection.—The PRESIDENT, having seen the case, said the child had an admirable limb. He had at present a case of fibrous union. He would not set up passive motion, fearing the result would be amputation; and he agreed with Mr.

Digitized by Google

Corley that he would not look for fibrous union, but would endeavour to obtain bony union, in which he had been successful.—Dr. BENNETT, replying, said he had attained his object in raising the question whether in dealing with excisions of the knee it was good surgery to have two strings to one's bow, rather than be bound down by the rigid rule of osseous union. He had not considered the question of shaping the surfaces. Leaving the patella he regarded as a source of danger, a focus of disease; but he would leave the tendon intact. The cases requiring the strictest rest were those rare ones of acute disease. The more suitable cases for excision of the knee-joint were those in which the disease had passed the acute stage, and where deformity existed, and for that class he would obtain a movable joint.

Dr. EDGAR FLYNN read a paper on Acute Traumatic Tetanus, and brought under notice a case which had been treated in St. Michael's Hospital, Kingstown. It was that of a labourer who had the middle and ring fingers of his right hand severely crushed. Symptoms of tetanus presented themselves on the fifth morning after the accident. The treatment relied on was half a grain of cannabis indica in the form of pill every second hour, with a mixture of twenty grains each of hydrate of chloral and bromide of potassium every fourth hour, to relieve the severity of the tetanic spasms. Inhalations of nitrite of amyl were used with very marked relief. Nutrient enemata, consisting of brandy, beef-tea, and opium, were given twice a day. Hypodermic injections of morphia were frequently given during the progress of the case, more especially at night. An ice-bag was applied to the spinal column. The patient underwent all the symptoms of acute traumatic tetanus in a marked form. He left the hospital six weeks and a half after receipt of the injury in good health, but very much emaciated.—Dr. F. A. NIXON mentioned an acute case in Mercer's Hospital, where the brother of the notorious Joe Brady, having suffered an injury to his foot and had his great toe amputated, recovered after a severe struggle for life.—Dr. M'ARDLE drew attention to five cases, two that were cured under Dr. Mapother's care and three fatal under his own. Dr. Mapother had administered thirty-grain doses of hydrate of chloral per rectum. In experimenting on the lower animals he used the electric current, and when applied from the nape of the neck to the middle of the lumbar region the spasms ceased. In his own cases the disease came on in one, two, and four days respectively after the injury.—Mr. THORNLEY STOKER'S experience was that nearly every case of tetanus occurring within eight or ten days after the injury died, and nearly every case that occurred twelve or fourteen days after the injury got well. He knew of no treatment that did any good in the acute stage.—Dr. M'ARDLE mentioned a case in which tetanus came on two months after the injury.—Dr. DOYLE said he had been called to see a case pronounced colic, but which he recognised as well-marked tetanus, and found that it arose from a neglected ulcer on the leg. Iodoform applications effected immediate improvement. Hydrate of chloral and bromide of potassium were administered in ten or fifteen grain doses every half hour, with or without morphia. The patient did remarkably well, and recovered.—Dr. BENNETT observed that where tetanus occurred two or three days after the injury, the cases were fatal; but where it did not, the disease must be subacute, and there was a fair chance of recovery. Where the wound was open, tetanus might at any time supervene. He had seen it occur in a case of compound fracture of the finger two months after the injury.—Mr. CORLEY commended Prof. Smith's classification—hyperacute, acute, and chronic. In the first the disease was immediate, and invariably fatal; the acute cases occupied the boundary line; and the chronic usually recovered. No doubt cases had recovered by nerve-stretching, but there was nothing more unphilosophic than stretching a nerve to cure disease of the spinal cord.—The PRESIDENT said the longest duration of any case he had seen was seventeen weeks, and the shortest was forty-eight hours. He had seen fatal cases of tetanus following burns thirteen days afterwards. In the case of a young girl in the City of Dublin Hospital during signs of tetanus, the treatment consisted of belladonna, hydrate of chloral, bromide of potassium, and ice to the spine; but as she was growing worse and dying, he stretched the median nerve, and the spasms ceasing, she recovered. In Dr. Flynn's case nerve-stretching had not had a trial, as both the great sciatic and anterior crural nerves ought to have been stretched.—Dr. FLYNN said the great sciatic nerve was stretched.

The Elements of Physiological and Pathological Chemistry. A Handbook for Medical Students and Practitioners. By T. CRANSTOUN CHARLES, M.D., Lecturer on Practical Physiology at St. Thomas's Hospital. London: Smith, Elder, and Co. 1884.

THE interest taken at the present time in animal chemistry, as regards its relation to both the normal and morbid processes occurring in the body, is shown by the numerous works on the subject that during the last few years have been brought before the notice of the profession. Twelve years ago no work in the English language existed in which the various operations required for the separation of the products of the tissues and fluids of the body were succinctly described. The only works then available for the student were Day's Physiological Chemistry and the translation by the Sydenham Society of Neubauer and Vogel's work on the Urine. The former of these, however, merely gave an account of the chemical processes carried on in the economy, and no attempt was made to describe the procedures necessary for the analysis of the tissues, fluids, &c.; whilst Neubauer and Vogel's work was limited to the qualitative and quantitative examination of the urine. The first systematic work on physiological chemistry, which endeavoured to meet the want felt for a simple and comprehensive laboratory guide for the study of this subject, was supplied by Dr. Ralfe early in the year 1873, in his book entitled "Outlines of Physiological Chemistry," which was followed a few months later by the larger work edited by Prof. Burdon Sanderson, assisted by Prof. Klein, Prof. Michael Foster, and Dr. Brunton, and which is known as the Handbook for the Physiological Laboratory. In 1880 Professor Gamgee published the first volume of his work on Animal Chemistry, a work which is not only a laboratory guide, but also deals in a most thorough manner with the chemical processes of the organism, and which, when concluded, will be undoubtedly the most complete treatise on the subject in the English language. In the work now under notice, Dr. Charles presents us with an outline of the most important branches of physiological chemistry, as considered under the heads of Nutrition and Foods, Digestion and the Secretions concerned, the Chemistry of the Tissues, Organs, and remaining Secretions; the Excreta, the Fæces, and Urine. Evidently no pains have been spared to render the work complete and accurate; but the author throughout seems to have been struggling with the difficulty of writing for medical students and practitioners (his announced intention), at the same time seeking to make his work a standard book of reference. To us, indeed, the handbook appears of rather too advanced a character for "students and practitioners," and is likely to prove of more service to the advanced student who has made animal chemistry a special study, and who has overcome the elementary difficulties, than to one who relies on it for an introduction to this difficult and complex study. Apart from this, we can speak very favourably of the work, which will make a place for itself in the literature of the subject. One great merit of the book lies in the numerous tables of analyses and the references to German authorities, which will be found exceedingly useful to those who are making physiological and pathological chemistry a special study.

A Statistical Inquiry into the Nature and Treatment of Epilepsy. By A. HUGHES BENNETT, M.D. London: H. K. Lewis. 1884.

THIS little book is a collection of three papers which have already appeared in the medical journals during the past three years. It is a careful collection of well-recorded facts and an example of painstaking and conscientious research.

Digitized by Google

It may well come under the category of those books which Bacon thinks worthy of being "chewed and digested."

The first chapter consists of a statistical inquiry into a variety of points in the etiology and symptomatology of the disease. This is so arranged that the percentage occurrence of the different phenomena is demonstrated. The second chapter is of special interest to the practical physician, and attempts to prove by precise numerical data the influence which the bromides exert upon the paroxysmal attacks of epilepsy. This is effected in the following manner. A large number of unselected cases form the basis of the observation. The details of each of these are carefully observed and recorded. The average number of seizures per month prior to treatment are noted, and the same is ascertained after the administration of the remedies. In this way no less than 117 cases have been under observation from periods varying from six months to four years, and elaborate tables are drawn up to show at a glance the result of the treatment. The general results of Dr. Bennett's experience are as follow: 1. "In 12·1 per cent. of epileptics the attacks were completely arrested during the whole period of treatment by the bromides." 2. "In 83·3 per cent. the attacks were greatly diminished both in number and severity." 3. "In 2·3 per cent. the treatment had no apparent effect." 4. "In 2·3 per cent. the number of attacks was augmented during the period of treatment."

The author, further, has constructed a number of special tables to show that under whatever circumstances epilepsy may exist, the general results of treatment appear to be the same, and he concludes that "the form of the disease, whether inherited or not, whether complicated or not, recent or chronic, in the young or in the old, in healthy or diseased persons, appeared in no way to influence treatment, the success being nearly in the same ratio under all these conditions."

In the third chapter the question of the effects of the prolonged administration of the bromides in epilepsy is discussed. The author points out that on this subject there is much difference of opinion, and this he thinks is due to the difficulty of distinguishing between the symptoms of epilepsy itself and the effects of bromide poisoning. As the result of his own experience of upwards of 300 cases he has come to the conclusion that the dangers supposed to attend the prolonged use of these drugs has been over-estimated. He furnishes a series of 141 cases, which have been under large doses of the bromides for continuous periods, varying from one to six years. These indicate that the proportion of toxic symptoms is comparatively small, while that of cases mentally and physically unimpaired is large. The writer is of opinion that the epileptic constitution is more tolerant of the effects of the bromides than is that of the healthy subject, and that bromism is always more prominently developed in the latter. He does not hazard any conclusion as to whether these remedies will finally eradicate the disease, but states his conviction that under favourable circumstances this is not impossible.
